The difficulties in the present situation seem to me to be brought a step nearer resolution when we find the proper answer to the question, What is the function of the medical profession? If we knew nothing of the antecedents of disease and accident we might be justified in answering that our function is solely to treat the sick and injured. But, as we have already noted, we know with certainty the approaches to disease and the ways in which the organism may be damaged, and, therefore, it becomes as much our duty to warn against the dangers as it is for the trackman who detects a broken rail. The service of the profession, then, should be not merely curative but also preventive; we are charged with promoting the physical and mental health of the people. If that statement is accepted, no difference will be found between the functions of the State and national agencies for the promotion of public health and the functions of the doctor in private practice.

Now the further question arises as to whether the private practitioner has fulfilled to a satisfactory degree his functions. The declaration has been made that he has not. It has been pointed out that the large amount of preventable disease in our population, the wide prevalence of uncorrected physical defects in our young men as revealed by the draft, and the ignorance among laymen of elementary principles of hygienic living are illustrations of the failure of the medical men to render their full duty to the communities they serve. The indictment has some justification. I do not believe, however, that physicians are alone at fault. Both they and the people of their communities have maintained the traditional attitude that the doctor's services should be limited to the care of the sick. It has not been expected that he would attend to ailments which are not called to his attention, or that he would look after people with the object of keeping them well and in a condition of high efficiency.

And let me ask still another question: Is not the theme we have been considering—the broadening of the sense of professional duty so that it includes the promotion of health—is not this theme the correct answer to make to the charge that doctors are failing to give the people proper care, and is it not the correct solution of the internal conflict between the private practitioner and the medical agents of the State? Clearly the physician cannot engage in the promotion of the personal health of his people without their cooperation. There is need for instructing the public in the advantages to be derived from securing health and physical efficiency instead of being repaired after a breakdown. But let people once learn that minor ills can spoil the keen edge of living, that it is well worth while to get into good physical condition and stay there, and that, like less complicated mechanisms, the human body needs periodic examination to determine whether it is standing the stresses to which it is subjected, and the welfare of our population would be raised to a level not hitherto attained. Many a physician learned during the war the importance of the morning "sick call" as a means of detecting the early stages of disorder. And every physician knows that it is in the early stages that he is best able to give the most effective treatment. If only through public education the physician might become the conservator of the family health, keeping the members well so far as possible and being ready to care for them when they fall ill, an enormous benefit would be wrought in the well-being of our population. And it would establish a new position for the doctor. He would become a leader in bringing about better modes of living. He would be a teacher of his people in ways of avoiding disease, and an even more effective collaborator than at present with the officials of the State in the protection of others against the spread of infections.

THE DOCTOR AS AN EDUCATOR AND COUNSELLOR.

It is obvious that such service as I have suggested would require changes in medical education. Greater emphasis would have to be placed on the standards of health, the elements of personal hygiene, the appropriate physical exercises at different ages, the influence of fatigue on bodily processes, the effects of worry and anxiety and deep emotional experiences, the dietary requirements for various conditions of life and labor, suitable clothing, and the best modes of securing rest and sleep—all these features would have to be understood and made as impressive to the lay mind as the transfer of infections, if we are to engage in an aggressive campaign for efficient living. It is obvious also that no such campaign can be waged until laymen are ready to coöperate in carrying it on. Already there are signs, however, that people are being awakened to the possibilities of individual health conservation. School inspection has shown to many communities that by means of tests, even though they may be applied by inexperienced persons, defects are discovered and remedied, with marked benefit to the children. Industrial physicians are familiarizing large bodies of industrial workers with the idea of preventive medicine applied to the individual. And the Life Extension Institute in New York has likewise done much to popularize the view that human well-being and efficiency should be sought and can be secured, if only physicians and laymen work together in striving for them.

At no point is an attack on physical weakness and defect and on disease itself undertaken with greater strategic advantage than in relation to children. In them many of the troubles with which the doctor deals are found in their incipency—the hopeful stage. Furthermore, childhood is a time of life when prevention and early treatment are especially important, because uncorrected faults may have far-reaching consequences. No better illustration need be given than that of imperfect vision, which, if not attended to, may lead stepwise to retardation in classes, discouragement, dislike of study and reading, and finally to departure from school, with a poor mental equipment and a handicap for future work. It is the early correction of such difficulties that saves the disappointments and distresses of later years. Again, if children are taught the principles and application of healthful living, they are likely to carry home both the knowledge and the practices which they have acquired. We must remember that children have a public opinion of their own, often more loyally supported than the judgment of their parents, and that through this opinion attitudes towards health measures are established which may influence the present generation but will be sure to influence the next. The securing of a wider diffusion of knowledge among children regarding public and personal hygiene is, therefore, one of the most powerful

and certain methods of promoting community welfare. In this relation, perhaps, the women physicians of the United States have an especially good opportunity to extend their professional functions.

If through popular education of children and adults the private practitioner should in the course of time be expected to practice both preventive and curative medicine in the families he cares for, his function as an educator and leader in public welfare would become much more important than it is now. His service as a diagnostician and doctor of medicine may still be in competition with others who treat disease, but his service as a developer and preserver of personal health would link in with the functions of the State. He would quite naturally be foremost in securing expression of popular will with regard to such public affairs as the betterment of living conditions, the eradication of evils threatening the integrity of the race, and the carrying out of programs for attaining a higher degree of physical and mental efficiency. Because his interest in the personal welfare of his people would have become primary, he would be in a strong position when questions affecting public welfare are raised.

THE DOCTOR AS AN INTERPRETER OF CONDITIONS AFFECTING PUBLIC WELFARE.

We are beset by questions affecting public welfare. Forgetful of the lessons which mankind has learned, and ignorant of the triumphs of preventive medicine, agitators are conducting active propaganda against the medical inspection of school children, against the use of preventive measures in such pestilences as smallpox and typhoid fever, and against any limitation of the liberty of carriers of disease. So long as we are merely practitioners of medicine our counsel with regard to the questions raised by these propagandists is not likely to be sought. If we should take on the larger service of being teachers and advisers of those we serve, we should quite naturally become interpreters of the facts on which are based the regulations and practices employed to promote the public health. We should find it one of our duties to point out the reasonableness of the rules which the neighborhood makes for its own protection. And although preventive measures necessarily trespass on personal rights, even the most extreme individualists must recognize the force of a public opinion which is based on an understanding and well-informed intelligence.

Another form of propaganda that is constantly going on is that against the use of animal experimentation for medical progress. Atrocious falsehoods regarding the treatment of animals in laboratories and utterly absurd denials of the benefits to mankind derived from application of the experimental method to problems of disease are widely circulated in our country by societies whose avowed object is the total aboli-

tion of so-called "vivisection." This effort hits directly at the most effective means that is known for discovery of the nature and treatment of disease. Success of the effort would be disastrous; for many problems still remain to be solved, and only through careful tests on lower forms of animal life can mankind be saved from continued disability and premature death. All these facts, long known to physicians, need to be explained to laymen. The doctor as an educator and adviser would be in an influential relation to the public as he told the story of medical progress and the debt we owe to lower animals for our saving knowledge of bodily processes and the ways in which they may be disturbed.

Still another menace to the best interests of public welfare lurks in the development of quackery and sectarianism in medicine. The special modes of treatment—such as the blue glass fad, magnetic tractors, naturopathy, osteopathy, chiropractic, etc.—have a natural history of being advocated by zealots, accepted by the uncritical and the seekers after novelty, of flourishing for a time and then passing away entirely or leaving in the body of medical practice any good they may have held. It has been customary for the medical profession to oppose the progress of these cults by advocating repressive legislation. Doctors seem at times to have regarded the license to practice medicine as a protection of their professional rights rather than as a protection of the public. Our attitude directly hostile to legislative recognition of new modes of treatment has been in the main neither dignified nor effective, and has led to unfortunate misinterpretation of motives. Again, the remedy lies in popular education, in an enlightening of people regarding the difference between cautiously progressive scientific medicine and pseudo-scientific propaganda. And again the doctor as an instructor and counsellor regarding the nature of disease would be in a favored place for teaching the limitations and dangers of ill-founded fantastic dogmas of both pathology and treatment.

This is, I believe, a momentous time in medical history. Knowledge has developed so rapidly and so extensively that no one mind can compass it. Practice has required such special methods and skill that no one individual can command acquaintance with all the procedures. Preventive medicine has demonstrated its values so thoroughly that everyone recognizes the propriety of State action when the public health is menaced. In this unsettling of traditional customs of medical practice, in this bewildering time when the relations of doctor and patient are continually shifting and there are conflicts of methods and uncertainties of future developments, what are we to do? I have tried to make clear that, no matter what happens, we must keep foremost our ideal of service. As practitioners we must engage in preventive medicine as well as in curative medicine, be-

cause in both ways we know how to help our fellow men. But industry and the State are likewise laying emphasis on preventive medicine, and the specialist is proving his claims to greater skill and insight when difficult cases appear. What, then, is to become of the general practitioners? Resolutions passed by medical organizations setting limits to this and that function of professional service will not determine events. Constructive programs are required, based on consideration of the needs of the people and the abilities of physicians to supply those needs. In the suggestions which I have offered that the general practitioner shall become an educator and an aggressive worker for health, there is much that is not new, or foreign to the labors he has long been performing. Only a stronger emphasis is laid on the private practice of preventive medicine than has been common in the relation of doctor and patient in the past. Other and better solutions of the problem of assuring adequate medical service may be suggested. And no full program can be laid down at this time.

THE MEDICAL PROBLEM IN RURAL COMMUNITIES.

The solution of these problems of readjustment of medical practice is only a part of the larger theme which we have been considering—the possibility of a better civilization in our country by medical attention to human needs. Another aspect of the same theme is beginning to loom large in rural communities. Studies made in different parts of the United States have revealed that the practitioners of medicine in the small towns are in the main elderly men—men whose age averages between 55 and 60 years. The fact is being recognized that the graduates of our medical schools are not being attracted to the country. The facilities with which they have become familiar in their medical course are not provided there—the library, the laboratory, the x-ray apparatus, the operating room and the hospital ward. I have known of physicians who have left rural practice because they felt that they could not conscientiously treat the sick unless they had the opportunities regarded by them as essential for making a thorough diagnosis. What is to be done under these circumstances? At least 40 per cent. of our population dwells on farms or in small towns. The economic stability of the nation depends on the products of the labor of these citizens. They should have just as good and just as well assured medical service as any other part of our population. Ten or fifteen years hence, when the elderly doctors have passed away, are these people to be left without adequate medical attention? Already in two New England States towns have guaranteed funds to induce physicians to come and serve them. Shall we look forward to a time when as a rule physicians must be subsidized to undertake country practice? Will State medical officers be sent to care

for outlying communities? The suggestion has been offered that the best mode of solving this serious problem lies in the establishment by communities—by counties or groups of counties—of public hospitals, offering all the conveniences needed for first-class practice. And the argument has been put forth that such a hospital in a center from which radiated a system of good roads could provide medical care for a wide area. Further, because of the common use of the hospital, physicians would be frequently brought together in consultation and conference, with the result that professional discouragement and decay resulting from isolation would be remedied and the young practitioner would be attracted. Again the solution which has been offered may not be the best one and on further examination may be shown to have grave defects. And even if it were regarded as the most satisfactory way out of the crisis which seems to be approaching in rural life, there would remain the necessity of persuading people of its desirability and of the reasonableness of spending public money for hospital construction and upkeep.

Such, then, are some of the puzzling questions which are of concern not only to the medical profession but to the public at large at this time. We, as servants of the common weal, should become keenly conscious of them and give our best thought to answering them. Attention to these questions will take us out of the routine of our daily duties, and bring us into relation to others who as public-spirited citizens are looking forward to and working for a better day. With them we must think out as clearly as possible the conditions which will be best for the welfare of all people and then strive to establish them. The opportunity for both professional and public service is a great one for us all, but especially for those who are just now entering on the duties of physicians.

THE FAILING HEART.*

BY PAUL D. WHITE, M.D., BOSTON.

INTRODUCTION.

HEART FAILURE consists of the inability of the heart to carry on a circulation sufficient for the ordinary life of an individual. It is thus a relative term. The amount of work routinely performed by one man may suffice to produce heart failure in another man who does not show any cardiac weakness in the habitual pursuits of his life. Mackenzie defines heart failure as "the condition in which the heart is unable to maintain an efficient circulation when called upon to meet the efforts necessary to the daily life of the individual."

The term "cardiac insufficiency" is, on occasion, preferable to "cardiac failure," for when the latter expression is used the average man in the community at once thinks of failure in its extreme phase when the victim is about to depart this life. "Decompensation" is an unsatisfactory term which I for one would discard with pleasure.

In general, there has been too much mystery about heart failure—in the books too much about back pressure, reserve force, restored compensation and all. The complication of the discussions of the subject has clouded it. There is still something to be learned about heart failure, but what is known may be, I believe, more clearly expressed than often one finds it.

How is the circulation normally maintained? By the proper action of the heart muscle and cooperation of arteries and capillaries. That circulatory insufficiency which is the result of failure of the peripheral circulation, and not of heart failure, I shall not discuss, except clearly to point out that these two causes—cardiac and arterial—of circulatory failure must be differentiated. Examples of peripheral circulatory failure are found in ordinary syncope, so-called surgical or traumatic shock, endarteritis and thrombosis.

TYPES OF HEART FAILURE.

Lewis has differentiated two types of heart failure or cardiac insufficiency, one in which dyspnea and congestion are the chief features, and the other in which pain, severe or mild, in the region of the heart, is induced by exertion. The former he has called "failure of the congestive type," and the latter "failure of the anginal type." Sometimes both pain and congestive symptoms and signs occur together, but more frequently they seem to be separate. It should be emphasized that angina pectoris or heart pain may be just as important evidence of cardiac insufficiency as edema; in fact, often much more so, if severe. The term "pseudo-angina" is a poor one and should be dropped. Many of the cases showing it prove later to have the so-called "true angina pectoris," dependent on actual sclerosis of the coronary arteries, and those that do not can be better classified, as I shall show shortly. There may, of course, be all gradations of both types of heart failure.

CAUSES OF HEART FAILURE OF CONGESTIVE TYPE.

I shall discuss now both types of cardiac failure or insufficiency from the standpoint of cause, diagnosis and treatment. First let me take up the "congestive" type. The etiology for heart failure is fundamentally the same as that for heart disease plus the necessary over-exertion or excitement which acts as the last straw to break the camel's back. The common causes of heart disease are, therefore, the common basic causes of heart failure. Arteriosclerosis, rheumatism, chronic hypertension, syphilis and thyroid intoxication are in about

*Read before the Norfolk District Medical Society, March 28, 1922.

that order the important factors. Sometimes two or three of the causes are combined in an individual case. But in the study of a patient with symptoms or signs of cardiac insufficiency it is not enough to make a diagnosis of heart failure; it is just as important to analyze and state the fundamental cause if it can be found, and if it cannot be found, it should be so declared. Also structural changes in valves and heart chambers should be ascertained and diagnosed, for they do make a difference in prognosis and treatment. The pendulum has begun to swing over from the former complacent attitude of the medical profession in the diagnosis of mitral regurgitation and cardiac dilatation towards simple expressions of functional capacity, but it tends to swing too far. The stethoscope is still a useful instrument, as are also the blood pressure cuff, the x-ray and the electrocardiograph. We must simply not read into their findings undue significance. In the presence of heart failure I like to know, for example, whether the patient is one showing also rheumatic heart disease, mitral stenosis and auricular fibrillation, or syphilitic heart disease with aortic regurgitation and normal rhythm. Prognosis and often treatment will vary according to etiology.

DIAGNOSIS OF CONGESTIVE FAILURE.

The first evidence of the onset of congestive failure is dyspnea on some ordinary exertion. From this symptom a steady progression to edema, cough and cyanosis may occur and of course when these develop the diagnosis becomes obvious. With dyspnea alone, however, diagnosis is not so simple. Probably just as frequently, or even more so, dyspnea is a symptom of nervous fatigue as expressed by the so-called effort syndrome. In young people this condition of exhaustion of an oversensitive nervous condition is very common. We found it everywhere in the army and I find it everywhere in civil life. Girls labelled "mitral stenosis" are as likely to have "effort syndrome" as mitral stenosis; young chaps labelled "gassed in France" are much more likely to have "effort syndrome" than any effect of the gas on their hearts; in fact, almost certainly so. This is a very vital matter to recognize, for the whole future of the individual may depend on the early and proper realization of the condition. I have seen a girl of about 20 who had been kept as an invalid for several years with the warning never to marry who had just as normal a heart as yours or mine, and perhaps more normal. She was of nervous temperament, showed dyspnea on exertion and had a sharp first sound which had been wrongly called a presystolic murmur. It required much explanation on my part to convince her that she was just high strung but normal as to her heart after the French! She had lived for years. Very helpful points in distinguishing between the two are the onset of heart disease and of effort syndrome

are that there is apt to be more palpitation with effort syndrome and that there is often actually more heart pain of one kind or another. Very helpful additional evidence against heart disease as the cause of the shortness of breath is the story in young people of dizziness with or without actual syncope. If a young girl comes to me, complaining of fainting, palpitation and shortness of breath, I should be right ninety-five times out of a hundred if I considered her a case of effort syndrome rather than of heart disease even before I examined her. The term "effort syndrome" is weak in that it does not express the effect of excitement on such hearts, often much more striking an effect than that from effort. Neuro-circulatory asthenia was a term used in this country for the condition during the war. Nervous heart is another term in use.

I should like to make one further observation about this very important condition of effort syndrome, and that is, that it may coexist with heart disease, especially in young people. I find almost invariably that the symptoms in such people are ascribed by the doctor to the heart trouble, when as a rule a considerable percentage, and sometimes even a great preponderance, of the symptoms are the result of the associated condition of effort syndrome.

Other less common conditions than effort syndrome, to be differentiated from heart failure, are hyperthyroidism and subacute or chronic infections, which after all really express themselves cardiovascularly as effort syndrome. Tuberculosis, subacute endocarditis, and low-grade septicemias are particularly apt to be mistaken for slight heart failure. Anemia, primary or secondary, and malignant disease are other conditions, and chronic nephritis still another, if producing toxic symptoms, to be distinguished from a failing heart. Chronic bronchitis, hepatic cirrhosis and phlebitis with edema may rarely simulate cardiac insufficiency. A recurrent acute endocarditis in an old rheumatic heart is particularly apt to be confused with heart failure. Careful temperature records and blood counts are often necessary.

What about asymmetrical failure of the ventricles? And how does the old back-pressure theory fit into it? There is little question but that in chronic mitral stenosis, where the right ventricle has hypertrophied preponderantly to maintain the much-increased pressure of the pulmonary circulation, the strain may finally become too great for it. It may begin to fail before the left ventricle does. This is not back pressure. It is just inability of the right ventricle to maintain a proper forward pressure. The lungs become more and more engorged and edematous, and the blood poorer and poorer in oxygen. This affects the whole body and, incidentally, through the coronaries the left ventricle, which eventually also begins to fail. Then general edema appears in the legs and belly, and finally

we have a picture of extreme failure of the whole heart. It is similarly conceivable that in chronic systemic hypertension (as opposed to pulmonary hypertension) the left ventricle, which carries the burden, may be overstrained and begin to fail. Edema appears, coronary circulation is interfered with, and so the vicious circle goes on with the right ventricle finally failing also because it is poorly supplied with blood. It appears to me that this explanation of asynchronous onset of ventricular failure seen in some cases is a reasonable one; it is supported by a good deal of evidence.

Whether or not it is possible to tell which coronary is thrombosed by evidence of the earlier failure of one ventricle than the other I do not know. At the present time I have under my care a man who a month or more ago had probable coronary thrombosis (evidenced by very severe prolonged pain requiring repeated doses of morphia and followed by acute pericarditis and paroxysmal auricular fibrillation and great weakening of the first sound, with an old history of repeated brief attacks of angina pectoris). He now has pulmonary edema with hemoptysis and cyanosis with little or no edema elsewhere. He may have thrombosis of his right coronary artery, or of that part of the left coronary which helps to supply the right ventricle.

TREATMENT OF CONGESTIVE FAILURE.

Now as to the treatment of heart failure of the congestive type. One of the very commonest conditions associated with this type of failure—and indeed in large part responsible for it—is auricular fibrillation or absolute arrhythmia of the pulse. When a patient with this arrhythmia is first seen, before treatment, the apical pulse rate is usually very high, averaging perhaps 150 per minute and fitting in every way the old term *delirium cordis*. In such a patient prompt and proper treatment results in such vast and striking benefit that its recognition and relief constitute one of the demonstrations of the real value of the doctor in the community. I dare say medical reputations in practice are not infrequently established by the fact that foxglove by its poisonous effect on the junction of the auricular muscle and the node of Tawara acts as a sedative to the heart. Thus only indirectly is digitalis a stimulant—by far its greatest benefit comes from its poisonous sedative action. And indeed it is worth while to recognize auricular fibrillation as an essential factor in the production of much heart failure of the congestive type. The failure results from the strain of a very rapid heart beat on a diseased or weak or exhausted myocardium. The speed is more important, I believe, than the rhythm; for once the rate is reduced circulation is restored in most cases in spite of the persistence of the irregularity. Simple as this may seem, the discovery in actual practice of improper treatment of the failing heart with auricular fibrillation makes

me feel that too much emphasis cannot be placed upon it. Usually too little digitalis is given or it is given too slowly. As one authority has said, many people have died as the result of digitalis therapy, because too little was administered. At times perhaps the actual quantity of dried leaf or tincture or infusion may have seemed sufficient, but a feeble leaf may be responsible for its inertness. However, I think it may be truthfully said that nowadays most of the digitalis preparations on the market are of good potency.

An example of the treatment of a patient with heart failure of the congestive type may interest you. It was to me a striking lesson. A woman of 55 years, seemingly on her death bed, I saw in consultation in an outlying town eighteen months ago. She was very ill, orthopneic, cyanotic and markedly edematous. She was raising bloody sputum. Her apex pulse rate was 164, absolutely irregular; her radial pulse 142, a pulse deficit therefore of 22. She had had rheumatic fever in childhood and for a year past had had palpitation, dyspnea and precordial distress, apparently somewhat relieved by small amounts of digitalis. She had become acutely worse two weeks before I saw her. Small amounts of digitalis having failed to help her, she was put on *crataegus oxyacantha*—5 drops every three hours, with 1/100 grain of strychnine and 5 drops of whiskey every half-hour. She was losing ground fast and it did not seem that she could live overnight. I found mitral stenosis and auricular fibrillation present, undoubtedly of rheumatic origin. She promised to be a favorable case for saturation with digitalis and I gave a hopeful prognosis. Her heart was obviously crying for digitalis (as shown particularly by the very rapid, irregular apex rate). We therefore began giving her digitalis leaf by mouth (and, by the way, it is very rarely necessary, even in such an emergency as this case was, to give digitalis by vein or under the skin). Three grains (0.2 gram) were given every four hours and the order was left to continue this dosage until the apex rate fell below 80 or until the patient was toxic (as shown by nausea or a coupled pulse). All other drugs were omitted.

The next day she was already better, and when I telephoned on the second morning I found she was wonderfully improved, the apical pulse rate 68 without deficit, but still irregular, of course, the edema vanishing like snow in the spring sun and the cough stopped. She could lie flat with comfort. This miraculous effect was accomplished, I am convinced, by the reduction in the pulse rate. The heart was beating 96 times less often every minute than it had been beating two days before. Just think what this means to a tired heart—in 24 hours, 138,000 contractions cut out!! No wonder the myocardium was recovering and the circulation restored. Shortly this patient was up and around, and within the

past month I have heard from her doctor that she is in very fair health.

In connection with this case I want to emphasize the importance of recording the apex pulse rate—it should always be done when auricular fibrillation is present. Both apex and radial pulse rates should be taken simultaneously by two observers, or else in successive minutes by one observer and the difference graphically represented, if possible; the difference is the pulse deficit. The reduction or melting away of this deficit under digitalis therapy is a good guide in treatment. Yet often one finds even in unexpected places that the radial pulse is the only pulse record on the nurse's chart. I remember one striking case in which, according to the chart, which I examined first before I listened to the heart, the pulse was recorded as 90-odd, feeble and irregular. In this case the apex rate was over 170 and auricular fibrillation was present. The institution in this patient of proper treatment, with relief, actually depended on the recognition of this fact.*

I do not believe in overdoing the matter—that is, in giving too big a dose of digitalis at the outset. In the first place, one may not be absolutely certain about possible digitalis already taken, and secondly, there is no particular point in making the patient nauseated, even though in the process the heart is vastly improved. Also rarely digitalis kills. Intense nausea and vomiting and the bigeminal pulse are indications that we are close to the danger point in digitalization—probably nearly 90 per cent. of the lethal dose has been given. There is a happy medium between the small doses of bygone days and the massive doses which we have recently tried in some cases. The size of the individual must be taken into consideration, particularly in the estimation of a proper dosage. Last night I saw a woman weighing only a few pounds over 80, who, having needed digitalis badly, had been given 3 grains (0.2 gram) of the leaf (a potent preparation in this case) three times a day. After two days she became intensely nauseated and had very severe gastro-intestinal symptoms for over 24 hours, with almost constant vomiting. When I saw her she was already getting over the worst effects of the drug and looked quite well, but was still nauseated. She had rheumatic heart disease, mitral stenosis and auricular fibrillation. Her apex rate had fallen from 130 to 58, and her circulation was almost completely restored. However, a person of her weight should have received a smaller total dose and she would have been better off. This illustrates the opposite error in the administration of digitalis.

One other case I want to cite here—a woman who entered the wards of the Massachusetts General Hospital 18 years ago. She had rheumatic heart disease and auricular fibrillation.

I have looked up her record and I find that she was treated for weeks and given tincture of digitalis in insufficient quantity and only at intervals. She actually was discharged from the hospital with edema still present and a high apical pulse rate (over 110), simply because the physicians in one of the best hospitals in the country, even as recently as this, did not know how to give digitalis and did not recognize the significance of auricular fibrillation. Under a very discerning clinician outside the hospital this patient improved and lived for years.

I cannot leave the very important subject of the treatment of heart failure of the congestive type without four more brief observations. First, it is essential that, after bringing the heart of a patient with auricular fibrillation under the control of digitalis, it be maintained under that control. Again, this sounds simple, but it is everywhere neglected. After a striking recovery under digitalis the patient with auricular fibrillation, whether arteriosclerotic or rheumatic in origin, goes on his way rejoicing. All goes well for a few weeks and then the pulse slowly climbs again, and with it comes another "break" in circulation. The process is repeated time after time; much work and money are sacrificed by the victim and undoubtedly his life is shortened. The rational procedure is to maintain digitalization in a patient once after securing it if the patient really needs the drug. Of course, this applies particularly to cases with auricular fibrillation. Give daily about the amount which is excreted. This is about $1\frac{1}{2}$ grains (or 0.1 gram) of the leaf in the average adult, who has been digitalized by about 22 grains (1.5 grams) in divided doses in two or three days. By maintaining this digitalization a patient may keep at work for years and undoubtedly live longer. It does no harm, so far as anyone knows, to take digitalis daily for years. Withering, more than a hundred years ago, knew more about the proper use of digitalis than many physicians do today.

The second point concerns the administration of digitalis to patients with normal rhythm. There is experimental evidence, and clinical, too, that even when the pulse is regular and fairly slow digitalis does help in failure of the congestive type. Apparently, in addition to its toxic effect to block off stimuli from auricles to ventricles, thereby resting the heart, there is also a direct stimulating action on the ventricular muscle. Such cases of congestive failure respond much less dramatically, however, to digitalis than do patients with auricular fibrillation.

The third point concerns the manner of giving digitalis and the use of other digitalis-like drugs in congestive failure. I have found that a good leaf in pill form by mouth is the most satisfactory therapeutic method. *There is no virtue of the tincture or of the infusion or of various costly pharmaceutical preparations of*

*M. J. Keane has pointed out that too much emphasis should not be placed on the apex pulse rate, since the time for the radial pulse rate is not constant, and the apex rate varies with the ability of the observer to count it. This is the case.

digitalis over the leaf itself, provided one knows that the leaf is potent. In hospital use the ordinary leaf is one-tenth to one-fortieth as expensive as various trade preparations, and apparently just as effective. Other drugs of the *digitalis* series—*strophanthus*, *scilla*, *apocynum* and *convallaria*—may be dismissed with the simple statement that for heart failure of the congestive type they are inferior—all of them—to *digitalis*. Other drugs, such as *strychnine*, *camphor*, *caffeine*, *adrenalin*, *cactus* and *crataegus*, are probably of no value as cardiac stimulants. To be sure, *caffeine* is a good respiratory and nervous stimulant and will at times break up periodic breathing such as Cheyne-Stokes, restoring a regular respiration; *adrenalin* will for the moment raise the pressure and dispel the circulatory failure of shock; and *strychnine* is a stimulant for the central nervous system; but there is little or no evidence that they affect the heart, and until there is I believe we should use such drugs only symptomatically—some of them, such as *cactus*, not at all. *Quinidine* is not a drug for the treatment of heart failure. Its sole function is to stop or prevent auricular fibrillation in selected cases.

I should like to digress here for a moment to say that I do not believe in giving a multitude of stimulants (so called) in infectious disease to "prevent the heart from failing." One of the most successful recoveries I have ever witnessed from severe exanthematic typhus was in a man who had two excellent nurses but no drugs at all.

Finally, the fourth point I want to make briefly is that besides the use of *digitalis* in congestive failure we have numerous other important measures. These are simple and widely followed, and I shall merely name them and then pass on to the final part of my talk: absolute rest in bed while there is failure; morphia if there is pain or great discomfort; veronal or bromides if sleeplessness; diuretics (*caffeine*, *diuretin*, *theocin*, *calomel*) if there is obstinate edema not vanishing with rest in bed and *digitalis*; reduction in quantity and richness of food (sometimes the extreme limitation of the Karell diet is helpful); catharsis (but not enough to exhaust the patient) and venesection in rare cases.

DIAGNOSIS OF HEART FAILURE OF ANGINAL TYPE.

And now I shall discuss briefly the very important heart failure of the anginal type. Here the only evidence of any sort may be the heart pain. There may be no other symptoms and there may be absolutely no signs of heart disease, and yet serious myocardial disease may be present. Mackenzie has recently told the story of a man of 60-odd who came to see him some six years ago because of heart pain. Although he could find no abnormality of the heart or circulation on physical examination,

he diagnosed coronary sclerosis and warned the patient. He did not see this man again until two years later, when the patient visited him once more and said that he was worse. He admitted that he had not heeded Mackenzie's warning, but had continued an active life. When asked why, he said that at the request of friends he had visited a prominent doctor in a far country. There many specialists had examined him and tested the contents of his stomach, bowels, bladder and veins; had taken x-rays and electrocardiograms, had determined his metabolism, and had tested the effect of various diets. All the results were negative and the man was pronounced normal. Because there was no instrument to measure and record the pain it was ignored. The man died later with angina pectoris. This is an extreme case, but it does support Mackenzie's contention that as accurate as seem to be our instruments of precision, they cannot reveal everything—they are still not infrequently too crude to show the more delicate pathological changes in the human body. Sometimes we are fortunate in the study of a doubtful case of angina in finding evidence of cardiac enlargement or aortic dilatation by x-ray, the extremely significant intraventricular heart block by electrocardiogram, the weak first heart sound at the apex by stethoscope or a positive Wassermann reaction. Occasionally all these findings are absent and yet the patient may die suddenly and show at autopsy coronary sclerosis, or even, in the severer cases, coronary thrombosis, with perhaps hemorrhage into the pericardium through a tear in a weakened infarcted ventricular wall.

Age at or beyond middle life and heart pain of almost any degree are the essential factors in the diagnosis. There may or may not be cardiac enlargement or high blood pressure or murmurs or poor sounds or pulsus alternans or peripheral arteriosclerosis (such as radial sclerosis or *arcus senilis*). Young people with heart pain almost always have the unimportant effort syndrome and must be differentiated. Such cases usually show also dyspnea, palpitation and nervousness. In these youths with effort syndrome sometimes the heart pain may be very severe and radiate even down the arms. As a rule, in an older person the pain is the essential symptom; it comes on as the result of exertion or excitement or the pressure of a full meal, before there is time for the development of dyspnea.

Acute or chronic abdominal disease (especially gallstones) often has to be differentiated from angina pectoris; rarely pleurisy or pericarditis may simulate it. Many attacks of "acute indigestion" in old people are simply angina pectoris.

There is rarely, if ever, edema except in the late stages, when, after years of angina, the congestive type of failure may supervene. The patient, however, rarely lives long enough to develop the congestive type of failure, but I

have seen recently a doctor, 70 years old, who began to have definite angina pectoris 12 years ago and who is now showing dyspnea and edema. As this case indicates, the condition is by no means immediately fatal, or even fatal in a few years, in all patients. It is one of the most difficult conditions in the practice of medicine to which to attach a reasonably accurate prognosis. An extremely rare combination of cardiac conditions is due to the coincidence of chronic auricular fibrillation and angina pectoris. This has been clearly recognized by Mackenzie and others. I have seen but one such case in arteriosclerotic heart disease. Paroxysmal auricular fibrillation with coronary thrombosis is not so rare.

CAUSE OF HEART FAILURE OF ANGINAL TYPE.

The cause of failure of the anginal type seems to be a malnutrition of the myocardium as the result of coronary sclerosis. Ordinary arteriosclerosis is the essential etiological factor, but syphilis plays an undoubted part in some cases. I do not believe that the condition is always the result of aortic changes (chiefly an aortitis), as suggested by Allbutt. I feel that myocardial irritation and disease as the result of temporary or permanent insufficient blood supply, because of abnormal coronary arteries, is a more important factor. The site of origin of the pain is interesting; it is often substernal, but also sometimes apical. Perhaps this variation is dependent on the site of the chief lesions—aortic or coronary. It seems probable that the angina of luetic aortitis and of coronary arteriosclerosis may be of different nature. This needs further study and analysis, and I have not had time tonight to go into the details of the variations in position and intensity of angina pectoris. It may be said, however, that the pain of true angina may be substernal or apical (more often the former), gripping or knife-like, constant or transitory. Interesting variations may occur, such as epigastric pressure, right chest ache, or numbness of the left wrist on exertion actually antedating substernal pain in the same case.

The mechanism of the production of the pain is not yet clear. It seems possible that a constriction of irritable coronaries may account for the usual attacks of angina, while for the prolonged terrible heart pain coronary thrombosis is responsible.* It is conceivable that coronary branches of various sizes may be irritable or thrombosed, giving rise to all gradations of symptoms and signs. When one says that coronary thrombosis is always fatal in minutes,

hours, days or weeks, one means that if a large enough artery is thrombosed the patient will die. I have seen at least temporary recoveries in several cases with probable coronary thrombosis.

Louis Gross of Montreal, in an excellent book on the coronary circulation (which it would benefit you all to read), has demonstrated the remarkably extensive coronary anastomoses in the human heart, particularly with advancing age, through the establishment of new vessels to supply the pericardial fat. He incidentally cites the case of an old woman who died of malignant disease. At autopsy it was found that her right coronary artery was completely thrombosed. Her myocardium was, however, almost perfectly normal as the result of anastomoses through the left coronary artery. She had in life never shown any symptoms or signs of heart trouble.

One further comment should be made on the subject of anginal failure before I end this talk with a brief discussion of its treatment. Nervous, high-strung people are probably more likely to show angina than placid individuals with the same degree of arterial damage. Their blood pressure, of the so-called essential hypertension type without nephritis, is apt to bob up and down readily at the least provocation. At such times of provocation their angina is apt to appear. I think this point must be borne in mind in prognosis—i.e., such people, if treated properly, may do fairly well for some time to come.

TREATMENT OF ANGINAL FAILURE.

Now as to treatment. Rest is essential—mental and dietetic, as well as physical; that and the relief of the pain. Nitroglycerine or amyl nitrite, the old stand-bys, are, of course, invaluable and should always be carried by the patient suffering from heart pain of the "anginal" type. Morphine should be given freely if necessary, and when much of it is necessary coronary thrombosis is probably the underlying condition. Digitalis is generally contraindicated in the anginal type of heart failure but may help a good deal if the heart pain is due to right ventricular fatigue in mitral stenosis or to the left ventricular fatigue in chronic hypertension. A light diet, particularly light in bulk, is of great importance; quantity is much more vital than quality. Five small meals a day, with the last one the lightest, are a good program. Avoidance of taxing business cares, as well as absolute omission of abruptness in physical activity must be advised. Rest will not only cause the cessation often of anginal pains but incidentally is by far the best treatment for hypertension which may or may not be associated with the angina. I have found, however, as low a blood pressure as 115 mm. systolic in marked coronary sclerosis. If syphilis is proved or likely, antiluetic treatment, begun with care, may be very beneficial.

*It is my belief that heart pain is of five types—first, the so-called true angina pectoris due to coronary arterial disease and constriction with resulting myocardial anoxia and exhaustion, relieved by nitroglycerine; second, aortic pain with aortitis; third, right ventricular fatigue as in chronic mitral stenosis, the pain being severe in location and not relieved by nitroglycerine but often helped by rest and digitalis; fourth, left ventricular fatigue as in chronic systemic hypertension or aortic stenosis, helped more by digitalis and rest than by nitroglycerine; and fifth, the pain in chest syndrome probably resulting from coarctative heart constriction in a person with low nervous threshold. The writer is continuing a study of an analysis of heart pain.

SUMMARY.

1. There are two general types of failing hearts—the congestive type and the anginal type.

2. All the causes of heart disease are likewise responsible for heart failure of the congestive type. The commonest causes are arteriosclerosis, rheumatic fever and allied conditions, chronic hypertension, syphilis and chronic hyperthyroidism.

3. A common and very vital factor in the immediate causation of heart failure of the congestive type is auricular fibrillation. Its recognition and proper treatment by digitalis is very important. Overexertion in normal rhythm may also cause failure.

4. Heart failure of the congestive type must be differentiated from effort syndrome, hyperthyroidism, acute infections, pulmonary disease and anemia.

5. Heart failure of the anginal type is the result of coronary sclerosis in general, with syphilis sometimes a factor. In this type auricular fibrillation is uncommon, except occasionally in paroxysms.

6. Anginal failure must be differentiated from the heart pain of mitral stenosis, of hypertension and of effort syndrome, and from acute and chronic abdominal disease.

7. Anginal failure may be present in a person with no signs of heart disease and no other symptoms.

8. Digitalis is, as a rule, not indicated in anginal failure. Nitroglycerine or amyl nitrite, morphia, but chiefly rest—physical, mental and dietetic—are the therapeutic measures to be followed.

9. The amount of cardiac reserve in both types of heart failure is often amazing, the patient sometimes living for many years after the first symptoms of heart failure have appeared.

A PRELIMINARY REPORT ON THE TREATMENT OF CARCINOMA OF THE ESOPHAGUS WITH COLLOIDAL SELLINUM.

BY ELMER B. FREEMAN, M.D., BALTIMORE.

[From the Digestive Clinic of Johns Hopkins Hospital.]

THE anatomical relations of the esophagus are such as to make the diagnosis of esophageal diseases very difficult and the treatment even more so. Also, when one considers the relations of the esophagus to the trachea and the thyroid in the neck, the left bronchus, the arch of the aorta and the heart in the chest, it becomes very apparent that the pathological conditions in these organs may, and frequently do, produce symptoms which are referred to the esophagus. It must also be borne in mind that diseased conditions quite remote from the esophagus may re-

flexly produce esophageal symptoms. Therefore, before discussing the treatment of carcinoma of the esophagus with colloidal selenium, I desire to briefly mention some of the symptoms of esophageal diseases and the special methods of study employed in the differentiation of the same.

Usually the first manifestation of esophageal disease is dysphagia, but frequently a lesion may have existed for some time before this symptom appears. This is true especially in carcinoma, while in spasmodic disease dysphagia is frequently an early symptom. When one considers that the esophagus is subject to marked mechanical irritations from coarse, irritating foods, to thermic irritation from hot and cold liquids and also to chemical irritations, it seems rather remarkable that pathological lesions do not occur more frequently; also, when it is remembered that the capacity of the normal esophagus is only 100 c.c., that the lumen is quite small, that for comfort in the swallowing act we depend very much on the elasticity of the esophagus, that, if much narrowing occurs at any point, obstructive symptoms occur promptly.

While dysphagia is the first symptom to appear in the majority of cases, it may sometimes be preceded by the sensation of fullness or discomfort or even by pain, that is dull and aching or sometimes acute and sticking in character, either in the sternal or epigastric regions. However, the slightest dysphagia or discomfort referred to the region of the esophagus should call for a very careful study, always bearing in mind that the symptoms referred to may be caused by pathological lesions quite remote from the esophagus. The dysphagia which is due to carcinoma is characterized in the beginning of the obstruction by difficulty in the swallowing of solid foods only, but after the disease progresses and the obstruction increases, even liquids are swallowed with great difficulty. Finally, complete obstruction occurs when nothing will pass through the esophagus.

On the contrary, spasmodic disease is characterized by a sudden onset and symptoms of almost complete obstruction which in a short time give way to normal swallowing, to be followed again by a return of obstructive symptoms. In these cases the obstructive symptoms are quite as pronounced with liquids as with solid foods. Associated symptoms depend mostly on the degree of dysphagia present. As long as the patient is able to take food in sufficient quantity, the condition remains quite satisfactory, but when they are no longer able to obtain sufficient nourishment, they begin to show definite signs of malnutrition and anemia and, in the carcinomatous cases, cachexia as well.

A routine physical examination gives us practically no information in regard to the esophagus, for one can palpate only a small portion of the esophagus above the thorax. This portion is so deeply located that even palpation is unsatisfactory. There is nothing to be made out

by percussion and the information gained by auscultation is unessential, but by this method we do sometimes hear a sound during the act of swallowing. The sound is best heard between the ensiform cartilage and the left costal margin. It is delayed or absent in obstructive lesions of the esophagus.

While the routine physical examination of the esophagus gives us no positive findings, the routine physical examination of the chest as a whole is very valuable in helping to rule out other pathological conditions which frequently produce symptoms, by pressure and otherwise, which are referable to the esophagus. The most important of these are thoracic aneurism, cardiac hypertrophy, enlarged bronchial glands, mediastinal growths and enlargement of the thyroid.

Due to the lack of information gained from routine examinations, it becomes necessary to resort to special methods of study. These are: sounding of the esophagus with a soft stomach tube or bougie, x-ray studies and esophagoscopic examination. All of these should be resorted to when a patient complains of dysphagia, however mild, or any abnormal sensations referred to the region of the esophagus.

The stomach tube is a valuable means of locating an obstructive lesion in the esophagus as it is soft and there is no danger of injuring the esophagus when the tube is manipulated carefully. No effort should be made to pass the tube if obstruction is met. By this method obstruction can be definitely located and some idea of the degree of obstruction may be gained.

The most valuable means of sounding the esophagus is with an olive bougie, passed over a silk thread as a guide. With a silk thread properly anchored in the small intestine, one may pass different sized bougies and in a measure work out the amount of obstruction present. One should never attempt to pass bougies unguided, for there is a great danger of making a false passage and puncturing the esophagus. This is especially true in spasmodic stenosis of the lower end of the esophagus in which there is pouching of the esophagus to the right, above the diaphragm. In these cases the unguided bougie does not enter the cardia but passes into the pouch which is frequently lower than the cardiac orifice, and the depth to which the tube passes gives one the impression that it has passed into the stomach. Any force used in the manipulation of the sound is likely to traumatize the esophagus and some cases of puncture have been reported. When the stomach tube fails to enter the stomach and a large bougie (passed over a silk thread guide) enters without difficulty, you may be sure that the obstruction is due to spasm and not to organic disease. Some difficulty in passing a silk thread into the stomach is experienced by most patients, but if the patient is instructed to swallow the first few feet very slowly, this will be overcome. In a few cases belladonna is helpful by overcoming the spasm. Not only can the degree of obstruction be meas-

ured but some information as to its character can be noted as well. In malignancy, one notes the marked resistance to the bougie and frequently the irritability and tortuosity of the canal, while in spasmodic stenosis there is a sort of elastic resistance which, with gentle pressure, gives way and permits free passage of the instrument. This difference in resistance is of the utmost importance in differentiating spasmodic from organic disease.

A careful x-ray study offers more in the way of diagnosis than any other method of examination. In most cases it locates the pathological lesion and gives us valuable information as to its extent and character. Before an x-ray examination is made, it is very necessary to empty the esophagus of its contents—otherwise, irregularities in outline and contour may be due to food and secretion retained in the esophagus. This is especially true in cicatricial stenosis and spasmodic disease. In cicatricial stenosis what is from an x-ray standpoint apparently a complete obstruction, may be found to be patulous after all of the food remnants have been removed. While evidence of obstruction with irregularity in contour is evidence of malignancy, it must also be borne in mind that malignancy, especially of the lower end of the esophagus, may occur without irregularity.

It is also perfectly well understood that chronic spasm in the lower end of the esophagus, while usually having a smooth outline, may show irregularity. Further, it must be borne in mind that spasmodic stenosis and carcinoma of the esophagus may occur together, and from an x-ray standpoint are very difficult to differentiate. While the evidence this method supplies is very valuable, it is sometimes misleading. Therefore, the x-ray interpretation must be made in the light of the clinical history, physical examination and the other special methods of study. Thus, I believe that to arrive at an accurate diagnosis, it is necessary in many cases to use all of the available methods of examination.

Most internists and many surgeons look upon esophagoscopy as a dangerous and difficult procedure and oftentimes unnecessary. We believe that there is very little danger and no difficulty in making an examination, if one has a thoroughly trained assistant, and we are convinced that this method of study is very helpful in differentiating esophageal diseases.

We have adopted a very simple procedure which has been quite successful. It is as follows: for two days previous to the examination the patient is given belladonna in dosage sufficient to cause some dryness of the throat. This, of course, lessens very much the secretion in the throat and esophagus and at the same time helps to overcome any spasm that may be associated with the pathological condition. In most cases, no further preparation is necessary, but in a few it is necessary to give $\frac{1}{4}$ gr. morphine and 1-150 gr. atropine, hypodermically, half an hour be-

fore the examination; also to make two or three local applications of ten per cent. solution of cocaine to the pharynx. After the patient is thus prepared, we proceed to empty the esophagus by using one of the newer suction apparatuses, to which is attached a small-sized stomach tube. This tube is passed down to the obstruction and then the contents aspirated. By this method we are reasonably sure that all contents have been removed. The patient is now seated on a low stool, the head held in the proper position and the esophagoscope is passed through the right pyriform sinus.

To make a careful esophagoscopy examination quickly one must have an assistant who is thoroughly familiar with the routine, as a faulty position of the head makes the introduction of the instrument impossible, and any attempt to pass the same is fraught with great danger to the patient. It is also very important to have the esophagus free from food and secretion—otherwise, secretion obstructs the view by coming into the lower end of the tube, making further examination futile. But if the patient is properly prepared and you have a thoroughly trained assistant, you will find that esophagoscopy is not difficult and will be a valuable aid to diagnosis in a group of cases that are sometimes very difficult.

In the clinic we have followed this simple routine as outlined and have found it, as far as our work is concerned, most satisfactory. We never make an esophagoscopy examination until the patient has had a routine physical and x-ray study. This procedure is followed so as to rule out, as far as possible, all pathological lesions that might be producing esophageal symptoms by pressure which, of course, contradicts any mechanical manipulation of the esophagus. With these conditions ruled out, one may proceed with safety.

While the x-ray is our most valuable means of diagnosis, still this method of study cannot replace endoscopy, by means of which one may obtain a direct view of the pathological lesion. Surely, if all patients with symptoms referred to the esophagus were seen early by the endoscopist, some pathological conditions could be diagnosed at a time when satisfactory treatment could be given.

We have seen small ulcers in the mucosa that were very difficult to diagnose endoscopically. However, the endoscopic appearance of most lesions, when once definitely established, is very characteristic. These small ulcers when situated near the cardia, I am convinced, are responsible for some cases of spasm of the lower end of the esophagus, and if these cases were subjected to an early routine endoscopic study, those that were due to ulceration could be diagnosed and treated before atony and dilatation occur. When one finds ulceration going on in the esophagus, then it must be decided whether or not the lesion is a simple ulcer or one due to tuberculosis, lues or malignant disease. Cases

of peptic ulcer have been reported, also those due to actinomycosis.

In simple ulcer one usually obtains a history of some mechanical, thermal or chemical irritation, but in a few cases there will be nothing in the history to indicate an injury to the mucosa. The simple or benign ulcer occurs most frequently at the anatomical narrowings of the esophagus which are also the most frequent location of malignant disease. Practically all of those due to traumatic injury from foreign bodies occur in the upper third of the esophagus, as ninety per cent. of the foreign bodies lodge in the region of the cricoid cartilage which is the narrowest part of the esophagus. The healing of a simple ulcer (unless very superficial) causes stenosis of the esophagus in varying degrees and the endoscopic appearance of the same depends on the degree of stenosis, the duration of the disease and the character of the irritant that has caused the injury. The most extensive injuries are caused by caustic alkalis.

If the stenosis is slight, the mucosa appears normal and there is no dilatation above the stricture. If the stenosis is of high degree, chronic inflammatory changes with or without superficial ulceration or abrasions will be noted in the wall of the esophagus above the stricture. Marked dilatation will also be noted. Cicatricial tissue in the esophagus is always paler than the normal mucosa. It may appear almost white. The appearance of the stricture depends upon the location of the scar. In some cases, a linear scar will be seen with a drawing-in of the wall of the esophagus. In other instances, the scar is seen to cross one side and cause a polypoid protrusion into the lumen. In many cases, the scar tissue almost encircles the esophagus, causing an annular stricture.

Esophagoscopy adds much to our knowledge in spasmodic disease of the esophagus. I believe that, in spasm of the upper end and early in spasm of the lower end, it offers more than any other method of study. By other methods it is difficult to make a differential diagnosis between spasmodic and organic stenosis of the upper end of the esophagus. An endoscopic study permits direct inspection of the diseased area which usually establishes the diagnosis.

In spasmodic stenosis occurring at the lower end of the esophagus, early in the disease, the endoscopic appearance may not differ from the normal. Late in the disease, the esophagus is very much dilated, the walls are atonic, the mucosal folds obliterated, the respiratory movements absent, the mucous membrane grayish in color, showing evidence of chronic inflammation with, in many cases, superficial ulceration.

The esophagoscopy appearance of cancer varies greatly according to the stage in which the examination is made and whether the growth is primarily in the esophagus or secondary to malignant disease in the adjacent viscera.

Jackson states that he has every reason to believe that the very early stage of esophageal

cancer occurs as a leukoplakia in at least a few instances, but that the opportunities for early esophagoscopy in cancer are so rare that there is no means of determining the frequency of such an onset. He states that, in these cases, the mucosa appears as though it has been burned with silver nitrate. In other instances, an early manifestation of malignancy is sub-mucosal infiltration which gives a sensation of increased resistance in the esophageal wall. This is always the early finding when the carcinoma involves the gullet from without; in these cases the mucous membrane remains apparently normal for a long time.

As the disease progresses, other local changes are noted, as: irregularity in the lumen, obliteration of the normal mucosal creases and folds and the absence of inspiratory and expiratory movements.

Later on, definite polypoid protrusions into the lumen, with consequent marked irregularity in the outline of the growth, are noted. At this stage, there is definite congestion of the mucous membrane and, in many cases, a beginning ulcerative degeneration of the growth. After ulceration has occurred, the appearance of the ulcer is not entirely dependent upon the carcinoma, but is partly caused by secondary infection with pyogenic organisms. A malignant ulcer is usually irregular in outline, the surrounding mucosa much inflamed, the surface granular and slightly elevated. It bleeds easily when sponged. Definite areas of necrosis may be found in the more fungoid and cauliflower types of neoplasms. Late in the disease, one is impressed by the marked rigidity of the diseased area, the tortuosity of the lumen, the ease with which bleeding occurs, the absence of scar tissue and the small amount of dilatation above the growth.

Endoscopically, a malignant ulcer may be confused with one due to lues or tuberculosis. In luetic ulceration, the following characteristics usually are seen: The edge of the ulcer is elevated and surrounded by markedly inflamed mucosa; the surface is frequently depressed; granulation tissue is not excessive and there is very little bleeding when the ulcer is sponged, although the surrounding mucous membrane may seem very much inflamed. The tuberculous ulcer is superficial, rather anemic in appearance; the granulation tissue is not excessive; the edges are not elevated; the surrounding mucous membrane is not congested and the surface does not bleed easily when sponged.

As yet thoracic surgery has done but little for cancer of the esophagus. Gastrostomy as a palliative measure prevents starvation, but a radical operation for cancer of the esophagus has been attempted only by a comparatively few surgeons and even in their hands it has not been very successful. However, with the recent advances being made in this branch of surgery, we believe that in the near future surgery will offer much to these patients.

Radium has offered more than any other method of treatment and, in the recent literature, some reported cures are to be found. Also much good has been done in a palliative way. However, with radium the problem of giving a dose large enough to penetrate the tumor mass sufficiently to destroy the cancerous cells in the outer zones without injuring normal tissue cells is still unsettled, and if the cells in the outer zones do not receive a lethal dose, they may be stimulated to greater activity, with the result that a slow-growing malignant tumor may be made to grow very rapidly.

If the attack against malignancy could be made through the blood stream, then it would be possible to bring the therapeutic agent into contact with all of the malignant cells.

Wassermann, working with mouse cancer, in 1911 and 1912, set out to solve the following problem: is it possible to influence therapeutically by intravenous injection, without injury to other cells of the organism, a rapidly growing tumor? Can one find a chemical compound which, after intravenous injection, will automatically leave the blood stream, attach itself to the tumor cells and destroy them?

The first experiments here to be reported were based upon the work of Gosio (*Zeitschrift für Hygiene*), Band 51, 1905) with sodium tellurium and sodium selenium, which give a red or black precipitate with living cells (due to reduction of salt to metallic state), but no precipitate with dead cells.

A. V. Wassermann readily proved that local injections (most easily with tellurium) would destroy carcinoma. However, this treatment is useless for tumor of inaccessible or unknown location, and intravenous injections are needed.

At first intravenous injections (tail veins of mice) were without effect, and it was thought advisable to provide for increased diffusibility by the addition of other chemical groups. For this purpose were tried several hundred compounds with the fluorescein dyes (eosin, erythrosin, cyanosin) combined with selenium and tellurium. These compounds were most unstable and most difficult to prepare. Finally, a combination of selenium and eosin was found to be very active. This substance is soluble in water and can be injected without fatal results in amounts up to 2.5 mgm. for a normal mouse of the average size (15 gms.). Following the injections the whole mouse becomes red.

Using this dose, in mice with neoplasm, these results were obtained: doses I and II, no visible changes; doses III and IV, the tumor softened to a fluctuating cyst and began to be resorbed; after dose V and VI the tumor gave the sensation of an empty sac and rapidly disappeared.

With too rapid resorption the animals died from toxæmia. After complete cure, no recurrences developed, but with incomplete treatment, early recurrences were the rule.

This treatment was uniformly efficacious with several strains of carcinoma (3 from Ehrlich, 1 from Schilling, and 2 spontaneous strains) and was even more effective with a strain of sarcoma from Ehrlich's laboratory. Of these tumors, none disappeared without treatment. Autopsies showed a red stained mass, or detritus, or fluid with pale or colorless tissue about it.

One can easily prove by putting small pieces of fresh tissue in the thermostat in selenium solution that the selenium is reduced by the living tissue and precipitated in the metallic state (fine black granules) particularly near the nucleus where the need for oxygen is greatest, but not reduced by the dead tissue. These results can be readily repeated with local injections into carcinoma in living animals. With intravenous injections of eosin-selenium, the action is mainly upon the cell-nuclei and there is very little leucocyte infiltration. The spleen of these animals frequently shows a deposit of this pigment, of even small masses of tumor detritus which have been carried there by the blood stream. This detritus is sometimes found also in the liver and lungs of animals which are responding to repeated injections. In a few cases nephritis occurred with necrosis of the epithelium.

The authors give warning that human tumors may not be susceptible to this drug, but state that mouse carcinoma can be cured by eosin-selenium in intravenous injection.

The poisonous nature of the preparation of eosin-selenium used rendered its direct application to human beings too hazardous. This difficulty was surmounted by the production of a colloidal suspension of selenium, the toxicity of which has been shown by animal experimentation to be negligible. Thus the way was opened to the therapeutic application of the remedy.

E. Watson Williams, in the *British Journal of Surgery*, 1920-21, makes the following statement: in many inoperable cases, the results obtained with selenium compare favorably with any known method of attacking a malignant growth by the way of the blood stream and are apparently equal to those of radiotherapy. All malignant tissue is affected, however inaccessible. As purely palliative treatment, the drying of ulcers and abolition of pain is a marked advantage.

He reported eighteen cases treated, with apparent arrest of the malignant process in six. Diminution in the size of the tumor could be verified in five more. The condition of the remaining ones was not conclusive. That is, apparent arrest and relief of symptoms followed treatment in one out of three cases and, in the whole series, the majority experienced considerable benefit.

From the possibilities of Wassermann's experimental work and the recent clinical report of good results obtained by Williams, we decided to carry out some observations with selenium in

carcinoma of the esophagus. We selected this group of cases because we believe them to be the most hopeless of all.

Colloidal selenium may be administered subcutaneously, intramuscularly or intravenously. When given subcutaneously, there is quite a little local reaction and the results have not been satisfactory. The intra-muscular method gives results similar to the intravenous route, though less promptly.

In the cases under observation, we are using the intravenous method. The general reaction is not alarming if one observes carefully the effect of the initial dose. The injection may be given in the office or the out-patient department of a hospital and the patient allowed to go home half an hour later. Repeated injections may be given into the same vein. If, for any reason, some of the solution gets into the subcutaneous tissue while giving the injection, the local reaction is negligible. The initial dose we have been giving is 3 c.c. This is followed on the second day by 5 c.c. If no reaction follows, this dose is given three times a week throughout the treatment. In this sized dosage there has been no cause for the least anxiety. So far, we have not given more than twenty treatments.

Following the intravenous injections in most cases there is, in a short time, a slight anaphylactic shock as evidenced by frequent pulse, weakness, nausea and occasionally a chill. There may be also increased difficulty in swallowing for a short time. This is thought by Williams to be due to an increased blood supply to the growth, and this to be secondary to a local deposit of selenium following the initial reaction which usually occurs within the first hour. There is in six to eight hours a general reaction, which continues for ten to twelve hours. During this time there is some rise in temperature, increased pulse rate, headache and general depression. Williams thinks this is due to absorption into the circulation of material destroyed by the drug. The initial shock or the general reaction which occurs during the first twenty-four hours usually only occurs after the first few injections or when the drug is given in very large and frequent doses.

In the cases under observation, there seems to be some improvement in symptoms. There has been relief from pain, dysphagia has become less marked, loss of weight has at least been temporarily controlled and, in one case, a very marked gain in weight has been noted. There has been marked psychic improvement which may be due entirely to the fact that some definite line of treatment is being carried out. However, I believe the improvement is partly due to the relief from pain which usually occurs after the first few injections. Also, the dysphagia is lessened and the patient is able to take more nourishment.

While the treatments are being carried out, careful esophagoscopy observations are made

from time to time. The appearance of the presenting part of the growth is noted—first, to determine whether or not there is evidence of increased blood supply to the part; second, if any sloughing or necrosis has occurred; third, if the esophagus has become more flexible or more patulous. We try to make these observations twenty-four hours after the selenium has been given. These cases are also studied by x-ray methods to determine, if possible, any change in the size and contour of the growth and also to note whether or not obstructive signs are becoming less marked.

As an adjunct to the treatment, dilatation is carried on by bougies being passed over a silk thread as a guide. This method of passing bougies prevents injury to the esophagus, which is quite likely to occur when they are passed blindly. The passing of bougies blindly is mentioned only to be condemned.

Our group of cases is too small to draw definite conclusions from, but we do feel justified in making the statement that in a certain group of cases this method of treatment may be useful.

It would seem from the literature that so far very little has been done with selenium in the treatment of carcinoma, and especially in carcinoma of the esophagus. If further observations were made in a large number of cases, conclusions might be worked out which would serve as a working basis in the future. We hope to follow out the work in a sufficient number of cases to try to formulate logical conclusions, not claiming at the present time anything more than a palliative treatment to be used in a certain group of cases which, up to the present time, have been, if not entirely hopeless, almost so.

We do not know whether or not the results obtained from this method of treatment will compare favorably with those where radium is used, but it must be borne in mind that for certain reasons, radium is not available to all patients suffering with carcinoma. If further observations on the use of selenium will establish its therapeutic value, then we have a method of treatment which is available for all cases.

The surgical treatment is to be given preference over all other methods when the technical difficulties of the same have been overcome, but up to the present time these difficulties have been so great that only a few surgeons have perfected a technique which justifies them in attempting radical operations for carcinoma of the esophagus. I do believe, however, with an earlier diagnosis, which will be made possible when the profession as a whole recognizes the importance of an early, careful study of all patients with symptoms referable to the esophagus, that some of these patients will be referred to the surgeon in time for operative treatment. This is especially true, I believe, of carcinoma of the lower end of the esophagus. I have seen one such case in the past year. In this patient the tumor was small, situated just above the

diaphragm, with apparently very little infiltration of the wall of the esophagus.

I am well aware of the fact that in many cases symptoms are overlooked by the patient or do not occur until the disease is well advanced, and little can be hoped for in this group. But, on the other hand, many times the presenting symptom of dysphagia or pain is overlooked by the physician or attributed to hysteria or some other nervous manifestation until the disease is well established and the most important time for study and treatment is passed.

PREGNANCY WITHOUT DEMONSTRABLE CERVIX OR CERVICAL CANAL, WITH REPORT OF CASE.

BY CHARLES J. KICKHAM, M.D., F.A.C.S., BOSTON.

Senior Visiting Obstetrician, St. Elizabeth's Hospital, Boston, Mass.

THE case reported below is unique from both an anatomical and obstetrical standpoint, and has some very interesting and instructive features.

Mrs. H., age 21. Para 1. Housewife.

Past History.—Always well except usual children's diseases. Periods of menstruation had been regular and normal since puberty, except severe pain at this time. Married about one year, and this her first pregnancy. Had severe pain at coitus from time of marriage.

P. I.—First seen when three months pregnant and physical examination showed a slight, nervous type of girl, but in fairly good health. Obstetrical examination showed external pelvimetry normal; vaginal outlet a little small, and patient very sensitive to examination; vaginal mucous membrane slightly congested and slight serous discharge in vagina; body of uterus easily palpable and softened and enlarged to about size of three months' pregnancy and in good position; careful palpation failed to show any uterine cervix or anything resembling it, or any cervical opening into the uterus; rest of pelvis seemed normal. The writer at this first examination felt a little bewildered to find a pregnant uterus and no apparent opening into the uterus. Nothing was said to patient, but she was asked to report again in one week. At this second examination, very minute search, both digital and speculum, failed to show any cervical tissue or any opening into the uterus anywhere along the vaginal walls, or any fold, behind which an opening might be hidden. After this examination anatomical findings, explained to both husband and mother of patient, and in matter of prognosis, the writer stated that since she had menstruated and had become pregnant, some uterine opening must be present and that when labor started, the softening of the lower segment and the pressure of the amniotic

sac, would probably dilate the lower uterine segment and, incidentally, the uterine opening. Patient had a disagreeable pre-natal period, with constant albuminuria and mild toxic symptoms, which was only kept under control by constant supervision. Patient went into labor at 2 P. M., with mild intermittent first stage pains and entered hospital; four hours later pains and uterine contractions had become regular every 3 min. and about 2 min. duration. At this time pains were of expulsive type, and membranes ruptured spontaneously with discharge of amniotic fluid; 2 hours later nurse reported that perineum showed signs of distention with each pain, and observation confirmed this. Patient prepared for vaginal delivery and rectal examinations made, which examination showed cephalic presentation, with head in pelvis, but no cervical opening palpable. Vaginal examination now made, and this confirmed rectal findings, with the addition that it showed uterine wall about $\frac{1}{4}$ inch in thickness entirely covering presenting part, no suggestion of uterine opening anywhere. Now came the question as to what to do? First thought was to incise uterine tissue over head, which was at pelvic spines, similar to vaginal Cesarean, and deliver with forceps; this was rejected because of danger of opening into abdominal cavity or cutting large blood-vessels which might be in an anomalous position, which is not infrequent with anatomical deviations from normal, and also came the question of mechanical difficulties with a small primiparous patient. After consideration it was decided that an abdominal Cesarean would be best. Lest my failure to find an opening into the uterus be the result of some personal fault, I asked my assistant to make a vaginal examination; this was done under careful aseptic conditions, and he, also, failed to find any cervix or cervical opening.

Patient now prepared for abdominal operation. Low incision made and peritoneal flaps dissected off lower uterine segment and held out of way with retractors; uterus now opened and foetus delivered; placenta and membranes delivered and exploration of uterus from within failed to show any suggestion of opening into vagina; uterus closed with two layers of sutures and peritoneal flaps approximated over uterine wound. Palpation of uterus through general abdominal cavity showed it to be normal and descend into pelvis with normal contour, and broad ligaments joined uterus in normal position; tubes and ovaries both normal. Parietal peritoneum closed and abdominal wall closed in layers in usual way; patient returned to bed in good condition and good ether recovery.

The writer wondered at this time what the next few days would show; what would become of the normal amount of clotted blood which remains in the uterus after any delivery; how could she drain the normal amount of lochia; would the small opening which must be present suffice as far as drainage was concerned, or

would even this small opening become clogged with a clot of blood or in some other way become occluded; would the usual influx of bacteria from vagina find its way through into the uterus and infect-retained clots? In a word, it was impossible to foretell what would happen; I just trusted in the Lord.

For 15 hours following delivery operation no sign of vaginal discharge or staining appeared, and then came a thin, serous fluid which gradually became blood-stained; this sero-sanguinous discharge kept up intermittently until patient left the hospital. About 24 hours after operation patient jumped a temperature of 102.5 and pulse of 120, but examination showed nothing definite to account for it. This temperature and pulse subsided in about 48 hours, and patient made a gradual recovery. Up to the 15th day patient ran an intermittent evening temperature, which was due partly to small necrosis at lower end of incision, with sero-purulent discharge, and to a slight pyelonephritis. Patient discharged from hospital on the 22nd day in fair condition; uterus well involuted and nothing in adnexa; wound well healed except small granulating area at lower end; general strength of patient had not returned fully, but she was up and about. The baby was placed on a formula before leaving the hospital, and at discharge was doing well.

This case proves that pregnancy can take place through a very small uterine opening, in this case so small as to be invisible; it proves that nature can take care of the involution of the uterus without the usual large amount of lochia which is discharged externally with a normal cervical canal; it proves the value of early examination in all cases, for in this way abnormalities can be discovered and the condition made known to the family, who cannot thus criticize the attendant later if difficulties arise.

VEIN PUNCTURE AND INTRAVENOUS MEDICATION IN INFANTS.

W. H. WATERS, M.D., BOSTON.

DURING the past decade vein puncture and intravenous medication have become so important that the physician unskilled in technique is greatly handicapped by his inability to properly perform these minor operations. About twelve or fifteen years ago it was not at all uncommon for many otherwise good men to be compelled to cut down upon some vein with a knife prior to an intravenous treatment, or even to obtain blood for a Wassermann test. Gradually, however, the technique has been so improved that such a radical procedure is most unusual, excluding, of course, some cases of transfusion where extreme anemia and a large needle at times render surgical incision still necessary. In the great majority of adults the median cephalic or basilic veins, either right or

left, even if not seen, can be palpated and punctured by the experienced operator. And in those cases where, on account of extreme adiposity or small veins, these vessels cannot be entered, it is almost always possible to find a suitable one at the wrist or on the dorsum of the hand. Occasionally the veins of the ankle or foot may be punctured where no others appear. The writer, in looking back over past years, working in a hospital of over five hundred beds, where he has had supervision of routine Wassermanns on all adults and of the intravenous administration of arsphenamine and other intravenous medication by the thousand, finds that the last time skin incision was found necessary was over eight years ago.

If, however, this procedure is usually relatively easy in the adult, the reverse is equally true of the infant. Under such circumstances the arm veins are small and are often neither visible nor palpable. Examination of blood, either for culture or for Wassermann, is equally important to that in the adult, while intravenous medication often makes all the difference between future health and a handicapped body or even life itself. Some other route must be found. Following work abroad and early work in this country, the posterior angle of the anterior fontanelle was used as a guide to enter the superior longitudinal sinus. Here is a vessel relatively fixed, closely situated to the surface and of sufficient size to be readily found. The technique will not be here detailed as it has often been described, only pausing to emphasize the great need of absolute asepsis. From that time to the present we have followed this route in about four hundred infants when obtaining blood for the Wassermann test.

There have been very few cases where we were unsuccessful in our endeavors, and in no instance has any injury, temporary or permanent, been noted, following the puncture. Following this simple puncture, we began the cautious introductions of arsphenamine and neocarsphenamine by the same route. This was done in some sixty instances equally without any demonstrable injury of any kind.

In the performance of the operation, one is working in close proximity to very important and vital parts, where any minor slip in technique may be most serious. An unexpected movement of the infant's head might result in a tear of the vessel wall, with resultant intracranial hemorrhage. Any error in asepsis might be followed by localized or general infection. And in medication, any small perforation of the opposite wall of the vessel might result in the escape of arsphenamine, or whatever is being used, into the subdural space, with most disastrous results. With us, therefore, the method was, of necessity, possible only to those particularly skilled in its application, and not practised for general adoption.

Even under such conditions, we began each operation with trepidation and finished it with

distinct relief when no unfavorable indication appeared.

In this uncertainty we eagerly looked for suggestions, and when the anterior and external jugular veins were brought to our attention we were only too glad to try them.

The results of the trial have been in every way so satisfactory that we now only very exceptionally have recourse to the sinus route. The technique is simple: The child is placed upon the table or bed, upon its back. A roll of cloth, often a roll of surgical cotton, or something similar, is so placed under the shoulders as to allow the head to be well directed backward. The head is then turned to one side or the other, dependent upon which jugular is selected. The operator stands at the head of the patient. This position usually exposes the vein, which can be seen just beneath the skin. Slight pressure, by the nurse, overlying the vessel just above the clavicle, renders the procedure more simple, while the fact that the infant at times cries, on account of the unusual position, often still further facilitates the ease of access.

The thumb of the left hand steadies the vessel by direct downward gentle pressure as the needle (gauge No. 20-No. 22), with the bevel edge upward, is inserted just beyond the thumb. The desired amount of blood having been obtained, the needle is withdrawn, and light pressure immediately arrests any bleeding. A small gauze and adhesive dressing is then applied. This process is usually simple in the extreme.

It is applicable during infancy and early childhood, whereas the sinus route is only available while the fontanelle remains open.

It does not have the possibilities of danger possessed by the sinus route, especially in intravenous medication.

From the psychological standpoint, a small pin-prick in the neck, often below the child's clothing, is much less fear-instilling to the parents than a puncture in the scalp or, as they often report it, "into the brain."

From all standpoints, therefore, when the usual vessels for puncture are unavailable or too small, in the infant and young child, the jugular vein offers a safe route and, when available, should be preferred to that of the sinus, *via* the anterior fontanelle.

A CASE OF SECONDARY PURPURA HEMORRHAGICA WITH REMARKABLE BLOOD CHANGES.

BY OLIVER H. STANSFIELD, M.D., WORCESTER, MASS.

This report is concerned with a case of streptococcal bacteremia, with secondary purpura hemorrhagica, remarkable for the apparent total disappearance of polymorphonuclear leukocytes from the blood.

The patient, a Jewish male of 23 years, was

admitted to Memorial Hospital, complaining of bleeding from the mouth and causeless bruises of the skin. The illness had begun three weeks before with an uneasiness in the stomach, without vomiting or diarrhoea. Four days later, jaundice had appeared, and had persisted up to the time of admission. Three days before admission, causeless bruises were noted, as well as bleeding from the mouth. On the day before admission bloody urine was voided. No other symptoms were present; particularly, there was no pain. The patient had been quite well for two years prior to the onset. Two years before, he had had a mild sore throat, and eight years before, a large boil on the nape of his neck. There was no other past illness; the family history was negative.

On examination, the jaundice, swollen lips with blood coming from the mouth and a "bruise" under the left eye were noted. There was no dyspnoea or cyanosis, or undue pallor. The man was lucid. The jaundice affected the whole body; many minute petechiae were found in all parts, with several larger hemorrhagic areas, one of which, on the right thigh, had a central infected area. Development and nutrition were good. No muscular, bony or articular lesions were found. The ears were dry, with good hearing. The sclerae were yellow, the eyes moved normally, the pupils were equal, 5 mm. wide, and reacted normally. The nose was dry. The lips were swollen, but not hemorrhagic. The teeth were in poor condition, with a false tooth inserted in one alveolus, and much caries. The gums were swollen and ecchymotic, with a slow ooze of blood from many points, but without sign of clotting. The tongue was brown coated. The fauces were ecchymotic. On the neck was the scar of an abscess. The thyroid was normal to palpation. The thorax was well formed and moved normally with breathing. The lungs were clear. The heart was not enlarged, had a regular rhythm, rapid (90 to 100) rate, and clear valvular sounds. No venous pulsations were noted. The abdomen was rather scaphoid, without tenderness, rigidity or mass to be made out. The liver was enlarged neither downwards nor upwards. The spleen and kidneys were not palpable. No enlarged lymph nodes were found. Tendon reflexes and sensory perception were normal. The temperature was 101, the respiratory rate 20.

Blood examination showed 90 per cent, hemoglobin by Tallquist's scale, 4,216,000 erythrocytes and 1700 leukocytes, with no polymorphonuclear cells or platelets to be found. The only leukocytes present were small lymphocytes. The red cells seemed strictly normal. Blood oozed, for several hours, from the puncture made for this examination.

The urine and feces contained blood, the urine being otherwise negative.

The next morning, the patient received by indirect transfusion 800 c.c. of whole fresh blood.

After this, all bleeding ceased, the petechiae disappeared and the larger purpuric spots began to do so. When a tooth—the false one—was removed two days later, a clot formed but did not retract.

Other examinations showed that a gingivitis which developed, was probably due to Vincent's organisms; the teeth, after special examination, were thought to be much affected by apical root abscesses. The nose and throat were not infected. Blood culture revealed an hemolytic streptococci bacteremia.

The further course of the disease resulted in death early on the seventh day after admission, hematuria reappearing on the sixth day. On this day, too, an embolus affected the right calf.

The white blood cell counts during this later course were 3800 on the fifth day and 3100 on the sixth. A short time before death, a count of 1850 was obtained. All counts were made from preparations from both of two pipettes.

In all, twelve stained preparations were searched but in none was a single polynuclear cell found, nor a platelet. In fact, all the leukocytes seen were small lymphocytes. No debris suggesting the possible presence of broken down cells was seen, and on looking over the counting chamber under higher powers of the microscope, only mononuclear cells were seen.

Probably related to absence of leukocytes was the appearance of the transfusion wound. This became white and necrotic by the third day, and on removal of the sutures, about 5 c.c. of transparent colorless fluid escaped.

On the sixth day, 4 c.c. of boiled milk was injected subcutaneously, but no effect, local or general, was obtained. (The blood count on this day was made some five hours after the injection).

Unfortunately, no post-mortem examination of any kind was allowed; but, in spite of this lack, the extreme degree of the blood changes make the case noteworthy.

New England Hospital Association.

ANNUAL MEETING MAY 17 AND 18, 1922,
AT BOSTON MEDICAL LIBRARY.

(Continued from page 699)

PITYRITIS FOR HOSPITALS.

BY DR. GEORGE H. STONE, EASTERN MAINE GENERAL
HOSPITAL, BANGOR, ME.

I HAVE been greatly disappointed, in my brief experience as an hospital executive in a small city, to learn that oftentimes the community does not manifest the interest it should in the affairs of its local hospital. I have found that the greater number of people have come to regard the hospital as a place of last resort to go to if they are sick, but do not realize the impor-

tant part it plays in the life of the community. If the street railway, telephone service, or other public utilities should shut down for even a brief period, a great clamor would be immediately aroused, demanding that steps be taken at once towards the prompt resumption of service. On the other hand, were the hospital compelled, through lack of funds, to close even a part of its plant, such action would receive only passing notice, and would be the subject, perhaps, of criticism, that such curtailment of service was due to extravagance in administration, and that such a step should have been taken long before; little realizing the severe blow which such a loss of hospital service would mean to the health of the community.

This apathy, or lack of interest, on the part of the general public has been the subject of much discussion in our board meetings. How should we overcome this indifference of the community towards the hospital and its needs? The one answer which seemed to offer the best solution was, that a campaign of education of the public through the local press should be undertaken, or, in other words—publicity.

A recent periodical in its editorial columns, deals with "Publicity" as follows:

"Nothing can be got in this country except through publicity continued over a long period. The tremendous and constantly growing advertising business in this country is a recognition of this fact. No matter how excellent an article, it has got to be advertised in order to be sold in large quantities. No matter how excellent a cause, it has got to have widespread publicity in order to be 'sold' to the people of the country."

It has been noticed many times in recent campaigns for funds for hospitals or other institutions, that such appeals have been preceded by vigorous educational campaigns extending over a period of weeks, and often ceasing abruptly after the drive has stopped. To my mind we should not wait until the need is apparent and then engage in a hurried campaign of education, but we should keep our hospital in the public eye on all occasions with a series of articles in the local papers, telling about what the hospital is doing to advance the cause of modern hospital service.

The community, upon which the very existence of the hospital often depends, is entitled to know, and should be told, everything about the institution. How is the hospital dollar spent? What are its needs? Why is a new laundry, power plant or nurses' home necessary? How much real charity work is the hospital doing? Are the trustees living up to their trusts? These are all questions in which the public is vitally interested, and may be properly asked by the community which the hospital serves.

How shall such a publicity campaign be conducted? First, the cooperation of the press must be obtained. This is no difficult, because most

papers are glad to publish anything that will be of benefit to the community in the development of local enterprises.

If nothing in the way of publicity has ever been done, we must start at the very beginning, possibly with articles dealing with the founding of the hospital, and following up with the story of its growth and expansion. The territory from which the hospital draws its patients, and the particular need for hospital service in this territory, should be set forth. Articles dealing with the value of the laboratories, the x-ray, and the training school for nurses; the important places these occupy in relation to the care of the patient and diagnosis of disease, should receive attention. All these may be used as leading articles appearing at least once a month. Between the publication of these stories, news items, such as the purchase of new equipment, the staff meetings, and general hospital activities should be given out from time to time, always keeping the institution before the public.

It is rather difficult, at least for myself, to write such articles so as to give them the appearance of news; so I have found that the best procedure is to ask for an experienced news writer to come to the hospital, and give him the facts, and let him write the stories, because newspaper men know how to present the details in the best way so that they will make interesting reading for the public.

It is needless to say that everything which is published must be absolutely correct, so as not to give wrong impressions. If the hospital is carrying a deficit, say so, and tell why. A deficit may be made to represent the hospital's greatest asset, if presented to the public in the proper way.

In our publicity work we should not lose sight of the fact that newspapers are always on the lookout for anything sensational. They want to know all about the latest accident cases, transfusions, and details relating to surgical operations. In this respect, we must remember the confidential relation that exists between the hospital and its patients, and we should be very careful not to give out any information which would in any way destroy this relationship, without first obtaining the permission of the patient or his responsible friend. Names of physicians should also be withheld in such instances, in order to avoid undue publicity or violating the code of professional ethics.

National Hospital Day, perhaps, affords us one of our best means of publicity. On this occasion the hospital may hold "open house," and invite the public to come and see for themselves the actual work it is doing. Many people took advantage of this opportunity in our city on May 12th, and I am sure the hospital made many friends on this occasion, because they had no idea of what modern hospital service means today. They developed a different viewpoint altogether of what hospitals are doing along the lines of education of physicians, nurses, and the

public, and I am sure the hospital will receive stronger support, if the need for financial assistance is ever presented.

To sum up: There is often a general lack of interest in some communities towards hospitals and their needs. The best way to overcome this, is through intelligent campaigns of publicity and education. These campaigns should be started, not merely for the purpose of appeals for funds, but should be kept up indefinitely; because the hospital owes this information to the public to which the institution looks for its support. Such campaigns are bound to result in a better understanding generally of the public towards hospitals, and, in the end, the hospital will be assured of better public support.

DR. HOWLAND: This is a very timely paper, and very interestingly presented. Hospitals have hidden their light under a bushel. They should let the community know what they are doing, taking due care that there shall be nothing sensational in the news.

MISS HASKELL: I should like to tell of our publicity work with reference to furnishing our new home. We had thought of appealing for funds in a regular campaign, but the city was in the midst of a textile strike, so it seemed undesirable to follow that method. We have a promising young minister there, and I told him a few things that I should like to have put before the public as to the needs of the hospital. This young minister wrote two columns for our local papers, one daily and one weekly, regarding the needs of the hospital. The response was immediate and gratifying. Friends of the hospital—and we have a good many—came, not to give what they wanted to, but to ask what we wanted them to give. And the result is that the entire children's department has been furnished by donation, and the living rooms and sitting rooms and dining rooms in the nurses' home have been furnished by donation; and we are constantly having small amounts, \$10, \$25, or \$30, to use for whatever purposes the superintendent wishes. We had in the past avoided publicity; but we have found that publicity is very much needed in our hospitals. People are interested in hospitals, and in everything that goes on in them, sometimes to the detriment of the hospital. If we could only put aside the things that should not go into the press, and have only the things that we most want put into the press, it would be a perfect God-send for the hospitals to be in the public eye as much as possible.

MISS EASTMAN, Eye and Ear Infirmary: I think about eight or ten little books were published, each one bringing in some little story about the Eye and Ear Infirmary, and asking for a donation. Last year that yielded between nine and ten thousand dollars. This year we followed that up by sending a note to contributors, reading something like this, "Last year you contributed—so much,—and we request that you do

the same this year." That has been going on about a month, and we are getting very good results. We are also sending out letters to people who did not give last year but who had contributed preceding that time. The Publicity Committee are writing a personal letter.

Q. You employed someone to write the little books; didn't you?

A. Yes; some of the stories were written by trained novelists, for which they were paid.

DR. BROWN: In our town the editor of our leading daily is very good about publishing anything we want published, and about writing up what should be written; though he is a little reticent about publishing anything as to the trustees not living up to their duties.

DR. SEXTON: With the inauguration of National Hospital Day a year ago, we published a little pamphlet, a four-page leaflet, giving in detail the organization of our hospital, the type of work we were doing, the per capita cost, the number of operations we did daily, or for the year, the number of patients that we had treated since the establishment of the hospital, free and otherwise, the daily operative cost of the entire institution, with other items I do not recall now. We placed a little receptacle for these leaflets at the front of the desk, and put a placard above it, saying "Facts which you should know about the Hartford Hospital. Take one." We have changed the nature of the information given on those leaflets about once in six months. About 200 of these leaflets are taken daily by visitors to the institution. Just how much good it does, I don't really know. It certainly sends into the community a certain amount of information that would not reach the people otherwise. We have never solicited contributions through that channel. As a matter of fact, we have only once gone to the public for funds. We asked two years ago, for half a million dollars, which they gave within a week. We shall not ask for another contribution for two or three years; then we expect to go back to the public, and ask for a similar amount. In the meantime, we feel that it is not wise to ask for contributions for any purpose whatever. These leaflets and other information we have been able to distribute has been purely along educational lines. We think keeping the public informed as to what we are doing will, when the time comes, be worth more to the hospital than it costs. We did not make a great effort at the last "Hospital Day," not as great as in previous years, when we had a window in one of the large department stores, and gave a lot of demonstrations on giving treatments, handling patients, nursing problems, etc. Our superintendent of nurses thought—and I think she was right—that that attracts curious people only, largely children and people who are morbidly curious. I don't think a demonstration in a store window ever attracts the class of people you want to bring to your institution. So we

omitted that this year. We advertised for a few days, in the local papers, that we would give a radio concert in our ward on Hospital Day, for the benefit of patients and their guests, and we extended the visiting hours an hour longer than usual, in order to give this concert; and we had a house full of people. Of course, the radio-telephone is very popular now, and a great many people have never heard a broadcasted concert given. I think it was curiosity to hear the concert, more than to learn about the hospital, that brought the crowd. Anyway, we had a lot of people who would not have come to the institution otherwise.

DR. HOWLAND: About what is the expense of a radiophone suitable for hospital use?

DR. SEXTON: I should not advise, knowing what I do, any hospital to purchase an outfit. I have just read, to my dismay, this morning, that an invention has recently been made that would relegate all apparatus we have recently purchased, and make it of no use whatever. So I advise waiting until the industry is more stabilized. The cost of an apparatus such as ours, where we have a central receiving station, and wires extending from this station to all our public wards, the same as the telephone, each having its own horn reproducing the concert, the same as a graphophone does,—the cost, with eight extensions, with the present type of apparatus, is about \$1000. Incidentally, the *Hartford Times* presented it to us. They took up a collection for five hospitals in and about Hartford. Two declined the outfit; so the entire donation which the *Hartford Times* collected will go to the three institutions. I think it creates a good deal of interest in a local paper when it takes up a contribution for hospitals. It was a purely voluntary effort on the part of the newspaper people. I think that radio apparatus will be very much cheaper in a little while. There are a number of inventions not yet placed before the public that will reduce the cost of it considerably, because of patents which will be superseded, or which will expire shortly.

During the afternoon we had put on our own concert. The amount of commercial business transacted during the day, the additional noises, etc., which naturally are picked up, same as the concerts are, made any attempts in the afternoon unsatisfactory. The novelty of the thing of course, added a good deal to it, and we felt that it was worth while. The graphophone gives a better piece of music than you can get from a broadcasting outfit, except late at night, too late to give to your patients. The novelty of the thing is more than the actual enjoyment received from the concert.

DR. HERSEY: We employ a woman who is a newspaper writer to handle the newspaper situation. The different newspapers used to call us up three or four times a day to obtain news, and when we were unable to give them sufficient

excitement to make headlines, they became peeved; so we found the best way was to employ this woman. She tries to get hold of the accidents and things of interest to newspapers. If we have any particular news we think would be of interest to the public, she puts that in the newspapers for us in a manner satisfactory to the papers.

In regard to the "hospital window," the hospitals about New Haven made a combined effort to have hospital windows during Hospital Day. We ran a demonstration on nursing technique, etc. This year I wanted to see what the situation was, and I watched the people who stood before the windows. I think the group interested this year were of a higher grade than those who had been interested in other years. I was quite strongly impressed with the fact that most of the people outside the windows, watching the demonstration, were young girls, who would make good nurses.

DR. PARKINS, Peter Bent Brigham Hospital: I think that Dr. Stone's paper is very apropos. Hospitals are passive institutions by tradition. No one can justify the investment of millions of dollars and the use of intelligent personalities without some definite and active program being carried out. The scope of the work is varied and it requires able minds to advance the standards in a steady manner. The service rendered to a community cannot be greater than it is willing to receive. Here is where advertising has its main function in teaching the community and individuals. Leaders in Hospital administration should have something to offer and be active in placing their services before both the professional and lay public. The idea of considering a hospital simply as a boarding house for sick people is medieval and cannot be tolerated in this day. A well planned advertising campaign will be a real benefaction to the community and the hospital. It is obvious that hospitals cannot take over all the methods and devices used in the commercial world, but many of the ideas can be used. Advertising must be considered in its broadest meaning in hospital work. A well built and well managed nurses' training school is a very real advertisement; courteous service, a capable dietary department and other departments well run are all sources of material for telling of an institution's worth. Another very interesting feature is the hospital as a health center. Why should other similar organizations be created alongside of a hospital? I believe that it is along the line of preventive medicine that the hospital has its greatest field in the future. Dr. Stone has given us some concrete suggestions, and I hope that many will act on them.

DR. HOWLAND: Mr. Borden, can you tell us how to get our needs before the rich people, so that they will remember us in their wills? Mr. Borden writes wills for people.

MR. BORDEN: Of course people making their wills are mostly older people who have grown up with certain pet charities, so that the older institutions are the ones most frequently remembered in wills. If you are looking for testators, the best thing to do is to catch the young people. In that connection, it is interesting to see how things work together in a hospital proposition. The construction of the nurses' home, and the use of the nurses' home, and back of it all is this idea that the training school for nurses has entirely changed; it is rapidly getting to be on a par with the girls' boarding school and the girls' college, and the product of the nurses' training school is a product that is coming more closely in touch with the social activities of the world. In other words, a necessary part of the education of the competent nurse today is education to meet people socially, people of intelligence, and to be able to talk with them in a manner to which they are accustomed. So the nurses' home should be a place of cultivation, as well as a place to learn primarily the arts of nursing; and, with that in view, we should provide social entertainment for the nurses in the nurses' home, by endeavoring to get them to provide social entertainments themselves. One way to do it is this: We get some of the young ladies connected with the women's board of the hospital to advise and assist the nurses in the ways of entertaining by teas, plays, and concerts, minstrel shows, and other things such as young girls in college are quite accustomed to. These young women who come into the training school to assist the nurses immediately get in touch with the hospitals, and by and by some of them are married and begin family life, with a knowledge of the hospital that they never could have got in any other way than by contact. So when you start a good thing, it reaches out in all directions. Of course, a great many of the hospitals in Boston advertise constantly the needs of the institution, and there is a reminder there, when a person is about to make a will, that the needs of the hospital are great, and that they are worthy objects of bequest. I think that is a very good plan, because people making wills can be thus given suggestions as to the proper distribution of their estate. I think more publicity in this direction would be desirable. I think a greater knowledge of the way the hospitals work would be desirable. It might be well for people to know what to anticipate when they went to a hospital. It seems to me that I should like to know what kind of accommodations I was to have, what I should carry with me, and that it would be worth while for someone who could write well to get out a little standard pamphlet about the needs of a guest at a hospital. It should be well written, and could be changed to meet the needs of different hospitals. Trust companies and commercial institutions do things like that. The general advantage of the hospital, and what might be ex-

pected could be written, and then specific things, rooms available, etc., incorporated by various hospitals. I think it might make an interesting publication. People are interested in patients, and would like actual information about what happens to the patient when he gets there. People pick up pamphlets and read them; and if you start in with a personal question, you could get them to read the whole proposition. It does seem to me that some bright chap or lady could start in and write up the general proposition of what should be in hospitals as a basis for publicity.

MAN: In view of the increasing number of estates now being handled by trust companies, it seems to me that the trust offices should be made fully acquainted with the work of hospitals that might be of value to us.

One source of publicity with us has been the giving of hospital talks before local organizations, such as women's clubs. One prominent citizen said that he had the impression that the hospital was a private banking institution; he said, "Hereafter, you can have any of my money when you need it."

WOMAN: We had an interesting campaign in Providence. The trustees decided that they must have a new building. At first they planned for a hospital of 100-bed capacity; then they decided to make it a hospital of 250-bed capacity, and to put it up to the people of Providence. They made a very careful statement, giving only facts, which they submitted to the people. They started their campaign, and the first published article was brought out in February. We had the coöperation of a very reliable paper, the *Providence Journal*. The work was undertaken by teams of 800 men and women. The object was to get one million dollars for building, equipment, and endowment. At the end of seven days they had \$1,225,000.

MISS METCALF, Lewiston Hospital: It may be of interest to hear what a small hospital has done. We have a board of directors. A little over a year ago, the oldest director of the hospital, and his wife, said they would give a nurses' home, provided the present directors would decrease the debt of the hospital at least \$60,000. We had a drive by the ordinary methods, and two of our directors gave up quite a number of weeks visiting in three counties, in Androscoggin, Franklin, and Oxford Counties. They visited prominent men in these counties and solicited funds, and in a very short time the sum of \$60,000 was promised; and our nurses' home was given by this director; also a hospital dispensary. Since then these men have continued the publicity work. They not only present the need of money, but give facts regarding the work of the hospital, and what it might do in the community; and the newspapers have contributed space for advertising the hospital and its needs. This has been produc-

tive of good; we have had more applicants for the training school, and an increasing interest in everything pertaining to the hospital.

DR. HOWLAND: Dr. Sexton said he had taken a leaf out of Mr. Statler's code. Mr. Statler's attitude is that his guest is always right. Dr. Sexton tries to make it seem that the guest at his hospital is always right; tries to avoid controversy. He says that if you send out a patient satisfied, that will be a means of getting the right kind of publicity. If he goes out dissatisfied over some small matter, such as an item on his bill, he is likely to give the hospital publicity, but of a very undesirable kind. Mr. Statler says "Our guests are always right."

QUESTION-BOX.

Signed Statements.

Q. Is it good form, when a patient is admitted to the hospital, to ask for a signed statement as to that person's responsibility for bills contracted? If so, what form can be used to best advantage? Is it good form for a hospital to sue a person for his bill? Is it customary to charge interest on a bill of long standing?

DR. SEXTON: We require someone responsible—it does not matter who it is—to sign a guaranty of payment of the bill of every patient admitted to our institution. They don't object to it. They come to us for service which they expect to pay for, and there has been, during my time as administrator, no one who objected to pledging himself to pay just debts. In the matter of collections, I don't believe we have had to sue anyone; but we do turn our accounts over, after a definite time, to a collecting agency. We have three form-letters which we send to them, after sending two statements of the account to which they have made no response. Then we send the first letter, which is very mild and as polite as we know how to write, calling attention to the indebtedness. If we don't hear in ten days, we send a letter a little bit stronger. If they pay no attention to that, in ten days, we send a third letter, saying, "We wrote you, on such a date calling your attention to the balance due at the hospital," and stating that unless immediate payment is made, the account will be placed in the hands of our attorney for collection. Notwithstanding the unemployment situation which has existed in the past year, we have not charged off any accounts which we would otherwise not have charged off,—no bad accounts. Our outstanding indebtedness last year was less than 5 per cent.

DR. HOWLAND: Haven't you a law in Connecticut that helps you in that matter?

DR. SEXTON: Yes; but we have never had to use it. We got it through the legislature at the last session. This law applies to people who leave hospital bills unpaid in the same way that

the law applies to hotel bills; imposing a fine of \$50 or thirty days in jail on anyone who hasn't satisfactorily adjusted their hospital account. It doesn't say they must pay it, but "satisfactorily adjust" it. It works.

DR. HOWLAND: We have a little contract form that we asked to have signed by the private patients, or those unable to pay regular rates, or those whose bills are to be paid by a relative, or someone who is to be responsible. We keep one copy and give the duplicate to the person who is responsible. This is a reminder that they understood what they contracted for. From private patients we intend to collect their bills, if possible. Our attorney thinks it is very desirable to put this contract in their hand and keep a duplicate, so that they cannot deny the agreement or say that they misunderstood. We formerly put down on the admission blank the amount the patient agreed to pay; now they sign their name. I should be glad to send a copy of our form of contract to anyone who would like it.

Hospital Records.

Q. What is your custom in regard to allowing patients' hospital records to be inspected and used, first, for court cases, and, second, for industrial accident hearings?

DR. HOWLAND: The practice is definitely defined by law in this state. We have no choice in the matter.

MR. BORDEN: You need not produce records in court unless you get a summons. Generally it doesn't pay to refuse, because you have to do it sooner or later, and may as well do it in the first place.

DR. RICHARDSON: The insurance companies and various people wanted our records. I tried to get a ruling from the city solicitor, but he didn't give any. I inspect each record, and if there is nothing in the record confidential or detrimental to the patient, we let them look it over. If there is something we think it is not best to show them, we give them such facts as we think proper.

DR. FAXON: At the Massachusetts General we have developed quite a routine method of handling this thing. The principle is that the plaintiff and the defendant are both entitled to a copy of the records. The plaintiff, if represented by a lawyer, must give that lawyer an authorization, and in that case we give them a copy of the record. A clerk is employed who does nothing else but copy these records. She is instructed, and, of course, at first you have to watch what she puts down very carefully. But after she becomes accustomed to what to put in and what to leave out, she makes very good copies, without much difficulty. Before they leave the hospital, all these records are in-

spected by someone connected with the administration. The charges vary from fifty cents for a certificate to \$3 for a copy. If the record is of great length, an additional charge is made. The reason we have taken this stand is because the records may be summoned into court, and we thought we might as well let them have the copy as to compel them to summons the hospital to bring the records into court, and cause the hospital the trouble of sending someone to carry the record. In addition, we many times have to send a man to court. He is not a doctor, but simply a representative of the administration. He reads the record; not being a doctor, he volunteers no opinion on what is in the record, except to tell how it was obtained. Industrial accident cases are handled just the same, because in this state the Industrial Accident Board has the powers of the court in summoning witnesses.

DR. HOWLAND: This afternoon the programme is to visit hospitals in Boston. I am sorry I can't tell you about some particular new thing in every hospital that you might want to see.

The South Department of the City Hospital has new isolation wards, with cubicles and modern sterilizing and utility rooms. The Children's Hospital, on Longwood Avenue, has a new ward. The Massachusetts General private ward, the Phillips House, is still in the very forefront of modern hospital construction. The Hospital for Women and Children, on Dimock Street, has a very large obstetrical service and a very interesting obstetrical ward. The Free Hospital for Women, in Brookline, has a new wing. The superintendents have not been asked to provide special entertainments; but they have all expressed themselves as very glad to welcome you if you care to visit them.

Report of the Committee on Nominations called for by the Chairman:

DR. RICHARDSON: The committee has had the usual difficulty in arriving at a decision; there are so many men and women well qualified for the positions. They submit the following:

For President: Dr. Louis A. Sexton of Hartford.

For Vice-President: Miss Mary M. Riddle of Newton.

For Secretary-Treasurer: Dr. N. W. Faxon, Boston.

Trustee for four years: Dr. Joseph B. Howland.

Trustees for two years, to fill the vacancy created if Dr. Sexton is elected: Miss Rachel G. Meltealf, Lewiston.

On motion made and seconded, it was *Voted*, that the Secretary be instructed to cast one vote for the election of the officers nominated.

The ballot being cast by the Secretary, the officers nominated were declared duly elected.

DR. SEXTON: I am deeply grateful for the

honor given me; but I feel very keenly that there are a good many older members of the Association who could do a good deal more for it than I. I shall expect to call on any or all of you for assistance, which I hope will be forthcoming.

(The retiring President was asked by the newly elected President to keep the chair for the remainder of the meeting.)

There being no further business, motion for adjournment was declared to be in order.

On motion moved and seconded, it was *Voted* to adjourn.

Adjourned at one o'clock p.m.

Medical Progress.

REPORT ON PSYCHIATRY.

BY HENRY R. STEDMAN, M.D., BOSTON.

DEMENCIA IN YOUNG CHILDREN.

ZAPPERT¹ reports two cases of infantile dementia from his own practice, and also gives condensed histories of five further cases communicated to him by T. Heller, who was the first to call particular attention to this form of dementia (1908). All seven cases are so similar that there can be no doubt about their belonging to the same group. After a period of normal or approximately normal development, the typical symptoms of the condition begin to appear in the third or fourth year. At first only peculiar inaccuracies of pronunciation are noted, but later speech becomes quite indistinct. In every case great unwillingness to speak developed, until finally spontaneous speech ceased entirely; also the understanding for spoken language was gradually lost. Restlessness, an excited condition, and sometimes hallucinations were common manifestations. Fear states were noted in some instances. The dementia continued to increase and ended in a few months in complete idiocy. The facial expression did not become idiotic, but remained, as a rule, rather intelligent. There were no bodily symptoms connected with the nervous system—no motor disturbances. The condition finally became stationary without impairment of the physical health. One of the children was the son of a physician. The diagnosis at first had been hysteria, but the course of this and other cases confirmed the progressive dementia. All were boys but one in this series.

NEUROPATHIC MANIFESTATIONS IN CHILDREN.

Eight cases showing marked evidences of the presence of the so-called neuropathic diathesis in infants and children are presented by Shannon.² In four of these cases, definite evidence of the exudative diathesis was also present, while in another case there was a positive history of such a condition in the past. The re-

maining three cases gave no evidence suggestive of the presence of an exudative diathesis. All the patients showed the presence of protein sensitization by cutaneous tests. All showed definite relief from the nervous symptoms on the institution of specific therapy directed at the proteins to which they were sensitive. In all but one of the eight cases the proteins concerned were those of foods contained in the dietaries of the patients. In one case animal emanations of pollen proteins might have played a part. In one case the nervous symptoms could be relieved or brought on by the exclusion from or the addition to the diet of the food to which the patient was sensitive. Evidence is presented showing that anaphylaxis is a sound, theoretic basis for the explanation of many of the symptoms of the so-called neuropathic diathesis.

NERVOUS AND MENTAL DISTURBANCES IN HEART DISEASE.

Jaquet³ mentions, among others, headache, inability to sleep: the patient cannot find any comfortable place in bed, or his cold feet keep him awake even with a hot water bottle. A brief tendency to dizziness and syncope is common, even in the young. A sudden transient inability to move hands or feet has also been observed, but it lasts only a few minutes. Lack of attention, a change in character, and actual psychoses are not rare. He warns that the physician may be responsible for them, by his heedless use of the terms "heart failure," "calcification of the arteries," etc., thus frightening the patient. Pleuropneumonitis in one woman had left cicatricial adhesions which were mistaken for grave organic disease, and the patient was warned to beware of all efforts or heart failure might result. She stayed in bed for nine months, not lifting a finger, before she could be convinced that she was not in grave danger. Then she got up and resumed an active life. Nervous dread and depression interfere with the action of heart tonics. Often, in heart disease, psychotherapy is the main thing. It frequently happens that a stay in a sanatorium is of great benefit. The patient loses his dread and restlessness when he knows that a physician is at hand day and night. This frequently tranquilizes permanently. In conclusion Jaquet warns against medicinal intoxication: he witnessed in two cases the development of a psychosis after the therapeutic administration of caffeine.

TREATMENT OF HYSTERIA.

Speaking of the treatment of hysteria, Head⁴ says: If possible, the patient should be removed from the usual surroundings, and new influences brought to bear. An attempt should be made to switch the dissociated part into the continuity of the patient's mental life. Every form of persuasion should be exercised to convince the patient that he is able to carry out the action he is convinced to be impossible. Never bully him

or accuse him of dishonesty. No one is a greater failure than the medical officer who wishes all hysterics could be shot at dawn. On the other hand, the firm diplomatist with subtle and demonstrable reasons why the patient can stand, walk, or feel, often produces miraculous cures. But it must never be forgotten that in a large number of cases, especially in civil life, removal of hysterical symptoms is only a prelude to the discovery of an anxiety neurosis. The causes for the suppressed emotion must be investigated, or the patient may be left in an even worse condition than that in which he was found. Do not harm the patient by antitherapeutic suggestion; carefully prune conversation, and do not think the diagnosis aloud. Avoid such words as "neuritis." Some diagnoses, such as "floating kidney," are more deadly than the disease. Avoid thinking in terms of surgery when dealing with functional neuroses. At the same time the most brilliant conversation is useless with an hysterical.

MENTAL INFLUENCE ON GASTRIC SECRETION.

Heyer⁵ research during hypnosis, a fine stomach tube in place, with continuous aspiration, demonstrated a remarkable variability in the acid content of the gastric juice in the same person at different times after both test meals and suggestion. The suggestion of pain, danger, recalling of war happenings, arrested at once the gastric secretion in nearly all the subjects. The suggestion of agreeable events, a spring day, winning money in a lottery, etc., never had the opposite effect, but had the same arresting influence, only it occurred more slowly. His research thus has demonstrated the law that any diversion of the mind, painful or pleasurable, from the act of eating, checks the secretion of gastric juice. The effect is more pronounced, the stronger the mental impression. In one patient with pure mania the gastric secretion was found constantly normal. In all the subjects, the stomach secretion increased at once in large amounts when a nutrient enema was injected. The distention of the rectum evidently promoted secretion in the stomach by reflex action, as all psychic factors were excluded, and the reaction occurred too promptly for the nourishment to have made its influence felt. The findings in this line suggest the necessity for giving nutrient enemas a drop at a time, with gastric ulcer, to avert this reflex action from distention of the rectum. His tables show, for instance, a drop from 10 or 20 or 18 to 0.5, 2 and 1 in the amount of gastric juice secreted under the suggestion of bombing, a railroad accident or the like. The drop was from 10 to 3 under suggestion of good news. Atropin given before or with the sham feeding checked secretion, but it did not seem to influence it when not administered until the secretion was well under way.

THE ENDOSECRETORY GLANDS IN PSYCHIC AFFECTIONS.

In 25 patients with mental disease Fauser and Heddaeus⁶ examined the thyroid, the suprarenals, the hypophysis, the genital glands, and in some instances also the thymus and the epiphysis. Seven patients belonged to the dementia praecox class; 12 were epileptics; 5 were imbeciles, and there was one case of senile dementia. In the thyroids of such patients goitrous degeneration was frequent; other changes were occasioned by concomitant affections (tuberculosis). The suprarenals showed, in part, senile changes and, in part, findings due to tuberculosis. In the hypophysis, there was found in various psychoses, a predominance of the basophiles over the eosinophiles in the anterior lobe, which is exactly opposed to the findings in healthy persons of corresponding age, and may possibly be regarded as a sort of retardation of function of the hypophysis. The genital glands, the thymus and the epiphysis showed no typical changes. It may be stated that only in exophthalmic goiter could infantilism of the endocrine glands be demonstrated histologically—not in psychoses such as they investigated. More extensive investigations may bring to light characteristic changes.

SCHIZOPHRENOID CEREBRAL SYPHILIS.

Urechia and Rusdea⁷ cite authorities and their own experience to confirm the finding that the symptoms of dementia praecox may be observed in the course of syphilitic disease of the brain and general paresis. These schizophrenoid symptoms may be transient or durable. In one case, from onset to death, the clinical picture was that of dementia praecox through the entire six-year course. Cases are known up to twenty years' duration, and lumbar puncture or necropsy first cleared up the diagnosis. In some of the cases both the Wassermann reaction and the spinal fluid findings became negative during a stationary phase. Catatonia is evidently the result of a certain injury of a certain part of the brain, but the morbid agent causing the injury need not always be the same.

GENERAL PARESIS IN THE AGED.

The process of involution already installed in the elderly imprints special features on progressive paralysis when it does not develop till late in life. The infection of 21 of 81 such cases in Jauregg's⁸ service at Vienna was of from twelve to over forty years' standing. In 27 per cent. of the total cases the mental derangement was of the persecution type. This paranoid form of general paresis seems to be peculiar to the aged. The optic illusions often took the form of animals, although there was no alcoholic basis. The hallucinations occurred mostly nights, and were often an occupational delirium. In short, the senile general paresis bears the impress of senile psychoses in general.

NONSPECIFIC TREATMENT OF GENERAL PARESIS.

Fischer⁹ reiterates his assertions that with sodium nucleinate we can count on an actual cure of a certain proportion of our cases of general paresis. His thirteen years of experience have shown 7.5, 16, and 56 per cent. cured without relapse in three series of forty, eighteen and sixteen patients with general paresis. Only 50, 40, and 8 per cent. in the same groups failed to show any benefit. He has found specific treatment as for syphilis entirely ineffectual. The prospects are better the younger the patient, and the shorter the duration of the paresis. Of all the means to induce the therapeutic leukocytosis, nuclein has given the best results to date. He declares in conclusion that a course of leukocytosis treatment should be given as a routine measure in prophylaxis of paresis to every syphilitic on concluding the specific treatment for the syphilis. He compares the results of treatment of paresis with tuberculin or by inducing malaria, or other means to stimulate leukocytosis. He advises repeating the course annually. In twelve cases all under 40 in which he gave over 10 gm. of nuclein, a cure was realized in 58 per cent. He gives the minute details for the treatment with which he has been successful. He begins with 2.5 c.c. of a 10 per cent. solution of sodium nucleinate injected subcutaneously in the arm or between the scapulae. After two or three days, 3 or 4 c.c. are injected in the other arm. Increasing the dose in this way, he reaches 10 c.c., and then the series is begun anew from the first. Three or four such series constitute the course. Fischer is professor of dermatology at Prague.

TREATMENT OF PSEUDOTABETICS.

It is often simple enough, says Kouindjy,¹⁰ to mistake a pseudotabetic for a genuine case of tabes, for the symptomatology in both instances is frequently very similar. Occasionally, this similarity extends even to a confusion in the findings of morbid anatomy. In spite of this, pseudotabes is a pathological entity easily distinguished from true tabes on account of its etiology, and, especially, of its course. Pseudotabetics are characterized by their tendency to complete cure, by tenderness on pressure of muscles, and by the absence of the Argyll Robertson pupil. Further, they can be distinguished by the different topographic distribution of anesthetics, which here diminish from the distal end toward the root of a limb, whereas in tabes they always show a radicular distribution. The treatment of election of pseudotabes must comprise treatment of the etiologic cause and also symptomatic treatment. Physiotherapeutic treatment occupies a predominant place in the second instance. Re-education must be considered the most rational measure, being calculated to combat at the same time both the motor disturbances of progression and the psychic state of pseudotabetics.

sults of a curative nature in cases of organic disease and new growths, by means of psychotherapy." Even cancer has not wholly escaped his skill. The text is interspersed with a large number of more or less fully reported cases. His many and invariably successful results are remarkably rapid, and he alludes to certain speedy cures as "magical." He predicts a "glorious time ahead" for those who will practice neuroinduction, asserting that "as a means of restoring will power it cannot be equalled in efficacy by any other known agency."

Medical men have little patience with panaceas and are therefore likely to receive these inordinate claims with scant favor. Moreover, the induction method, based as it is on a questionable psychology and a none too original technique, will hardly be generally accepted as a dependable guide in psychotherapy.

Diseases of the Skin. By HENRY H. HAZEN.

Second edition: C. V. Mosby Co., St. Louis. 1922. Price \$7.50.

This book differs markedly from most others on this subject in that it is written consistently from the general practitioner's point of view. He has simplified and condensed the chapters on anatomy and physiology, etiology, pathology, etc.; his chapters on treatment and hygiene are decidedly to the point. The arrangement of the succeeding chapters differs from that of most other works on the subject, being less scientific but much more accessible to the practitioner who wishes to identify as well as learn about cases that puzzle him; the first group takes up diseases due to external causes of all sorts; next, systemic infections, as syphilis and the exanthemata; the toxæmias; diseases due to blood vessel, lymphatic, and nerve changes; diseases due to foods, infantile eczema and pellagra; eczema; then a series of chapters each covering those conditions of unknown origin having the same general type of lesion, as papular and nodular, bullous and vesicular, etc.

The book is simple, very readable, takes up a sufficient length and in satisfactory detail the skin diseases more frequently met with. The illustrations are excellent throughout, the subjects well posed; the very large number of subjects chosen from the colored race makes a valuable addition to the worth of the book, as many dermatoses certainly differ considerably in the light and dark skins. A very few excellently chosen photomicrographs of striking lesions are included, leaving to the more voluminous and complete works the great mass of details useful to those who wish to become advanced in this field. The book has been largely rewritten for the second edition and some new material added.

Ten Post-Graduate Lectures, Delivered Before the Fellowship of Medicine at the House of The Royal Society of Medicine. 1919-1920.

With a preface by THE RT. HON. SIR CLIFFORD ALLBUTT, P.C., K.C.B., M.D., F.R.S. New York: William Wood and Co. 1922.

This altogether admirable book contains the text of ten lectures; printed clearly and cleanly upon two hundred pages of good flat paper; a good index is added; illustrations have been omitted.

In the recent Harvard-Oxford debate, the intelligent observer could easily note the very considerable differences which exist between the methods of public spoken discussion in two of the leading universities of the world, representing two of the great present divisions of the English-speaking world. These ten lectures at present under discussion, show equally distinctly some of the differences which exist between Medical books and writings of the same two great groups. And although the verdict in the debate was in favor of America, a goodly minority in Symphony Hall that night believed that in the matter of really worth while oral discussion, and in its method, the young Englishmen were far ahead of the young Americans—so, too, many thoughtful American readers of English Medical writings admire very greatly the style and literary craftsmanship which they find so often in the English papers, and which is so often and so unfortunately lacking in American monographs of parallel aim. It is lacking very largely because we are too much in a hurry, and because too few of us enjoy any considerable degree of Medical leisure. Every one who reads the *Boston Medical and Surgical Journal* should also read these ten lectures. Every one of them is interesting and most of them are extremely valuable.

Atlas of Syphilis. By PROF. LEO v. ZUMBUSCH of Munich. William Wood and Co., New York. 1922. Price \$15.00.

The atlas contains 49 illustrations of cutaneous syphilis taken directly from nature by color photography, ranging from the primary lesion, of various types and in various situations, through the secondary, transitional, and late manifestations; also five of congenital syphilis. Ten pathological specimens, including four photomicrographs showing treponemata, are included in the book. There is a brief paragraph of explanatory text with each. Rare types of lesions are not included, as the atlas is intended primarily for the student and general practitioner. The posing and lighting show skill and patience on the part of the author. The colors, unfortunately, have not come out true, yellow being too prominent in practically all the plates; otherwise the technical

execution is excellent. It should be useful for teaching and for those to whom syphilitic cases do not often present themselves.

A CONTRIBUTION TO THE QUESTION OF THE LEUCOCYTE FORMULA IN MALARIA.

SWAN, JOHN M. (*American Journal of Tropical Medicine*, July, 1922) writes that differential counts were made of 68 blood smears from 55 cases of malaria including all three varieties of malaria. The result showed that an increase of the large mononuclear cells is not constant in malaria either in the acute stage of the disease or in carriers. If, however, the presence of malaria is suspected and an increase of large mononuclear leucocytes is found "it seems reasonable to assume that the patient has or has had malaria." [G. G. S.]

THE RELATION BETWEEN SYPHILIS AND YAWS AS OBSERVED IN AMERICAN SAMOA.

PARHAM, J. C. (*American Journal of Tropical Medicine*, July, 1922) writes: "Evidence is adduced against the duality of yaws and syphilis and the view advanced that yaws is 'stone age syphilis.'" [G. G. S.]

SHOULD GANGOSA BE REMOVED FROM THE NOMENCLATURE OF TROPICAL MEDICINE?

KEBE, W. M. (*American Journal of Tropical Medicine*, July, 1922). The writer believes that the lesions to which the term gangosa has been applied are in reality late manifestations of syphilis or of yaws and that consequently the term gangosa should be eliminated. [G. G. S.]

THE IMMEDIATE INFLUENCE OF ALCOHOL INGESTION UPON DIABETIC GLYCOSURIA AND BLOOD SUGAR.

FULLER, L. S. (*Jour. Metabolic Research*, 1, 609, May, 1922), found that alcohol reduced both hyperglycemia and glycosuria in most of his mild or moderate diabetics, but usually not in those of great severity. The effect was most marked when alcohol was substituted for the caloric equivalent of fat, but was also frequently manifest when alcohol was added to the previous diet. Table III is really quite striking. The objection may, however, be made that the patient was retaining water in the body, and probably sugar at the same time, which might be only temporary storage. [H. G.]

THE INFLUENCE OF THE THYROID IN DIABETES.

AULTON, F. M. (*J. Metabolic Research*, 1, 619, May, 1922) concluded from the literature and from new observations on dogs that thyroid excess may aggra-

vate diabetes, but does not act as a cause; that thyroid deficiency may diminish glycosuria and hyperglycemia but probably only as a result of injury or cachexia; and finally that the general trend of the evidence has steadily reduced the supposed rôle of the thyroid in diabetes, especially as regards antagonism between pancreas and thyroid. [H. G.]

CLINICAL OBSERVATIONS CONCERNING PROGRESSIVENESS OF DIABETES.

SHERBILL, J. W. (*J. Metabolic Research*, 1, 667, May, 1922), reported in detail five cases of the youthful severe type, concluding that even these were opposed to the belief in a mysterious, spontaneous progressiveness. [H. G.]

THE CAUSATION OF EPIDEMIC DROPSY.

ACTON (*Ind. Med. Gazette*, Sept., 1922) makes a preliminary report on his studies of epidemic dropsy in India. This disease is characterized by localized oedemas, chiefly affecting the lower extremities, and not associated with signs of peripheral neuritis, thus differentiating it from beriberi. It is closely associated with an exclusive or almost exclusive rice diet. Both the quantity and the quality of the rice eaten are important factors. The disease is most common where the consumption of rice is greatest. Its peculiar distribution among middle-class Bengali Hindus indicates that the poison is formed during the seasoning process. These people prefer well-seasoned rice because it is sweeter and more easily digested. Seasoning consists in the splitting up, by bacterial action, of the vegetable proteins and carbohydrates into the more soluble proteoses, peptones and sugars. Seasoning is more apt to occur in polished rice, where the fruit is injured during the milling and, during the monsoon months, owing to temperature and humidity. When rice is boarded in hot, damp godowns, decomposition progresses further with the formation of polypeptides, amino-acids and finally toxic amines, which cause the dropsy. The prevention of this disease consists, therefore, in the elimination of seasoned rice from the diet. [L. D. C.]

DIAGNOSIS OF ACUTE GASTRIC AND INTESTINAL DISEASE.

SCHNITZLER (*Wien. Klin. Woch.*, June 22-29, 1922) discusses at length the entire field of diagnosis of acute inflammatory and mechanical diseases of the abdomen, involving the alimentary tract. He also reviews the principal indications for surgical procedure. The article is an admirable brief summary of diagnosis and treatment of the acute abdomen. [R. M. G.]

TREATMENT OF FEBRILE ABORTION.

MARX (*Wien. Klin. Woch.*, July 6, 1922) summarizes his treatment of febrile abortion in private practice as follows:

1. In incomplete febrile abortion with a free uterus and open cervix, immediate curettage should be performed.
2. With a closed cervix, the uterus may be emptied spontaneously by the use of quinine, but in the event of hemorrhage or rising temperature, evacuation by dilatation and curettage is indicated.
3. If the temperature falls and remains normal, the uterus may be emptied immediately.

1. When the infection has extended beyond the uterus, palliative and expectant treatment is indicated. [R. M. G.]

VENESECTOMY AND TRANSFUSION IN OBSTETRICS AND GYNECOLOGY.

WERNER (*Wien. klin. Woch.*, July 13, 1922) discusses the indications and contraindications for phlebotomy and transfusion in obstetrics and gynecology. The advantages of transfusion in acute, severe hemorrhage are obvious. Like many modern obstetricians, the author seems unduly enthusiastic about the benefit of venesection in eclampsia. [R. M. G.]

CENTENNIAL OF GREGOR MENDEL.

REICHEL (*Wien. klin. Woch.*, July 20, 1922), on the hundredth anniversary of the birth of the great Mendel, summarizes his fundamental contributions to our knowledge of heredity, and points out its basic significance for the future of the science of genetics. Like many geniuses, Mendel died without seeing the importance of his discoveries appreciated. It was the medical profession which first realized and applied the principles of the theologian-scientist. [R. M. G.]

HYPELOPHONY.

GEURINA (*Wien. klin. Woch.*, Aug. 3-10, 1922) describes, under the name of hypselophony, a new method of pulmonary auscultation, based on a study of the overtones, which tend to become emphasized, while the basic tone recedes, over consolidated areas. He discusses various phenomena connected with this method, which seems of value in the study of tuberculosis. [R. M. G.]

GALVANO-PALPATION AND ROENTGEN RAYS.

KAMANE (*Wien. klin. Woch.*, Aug. 17-24, 1922) describes a method for the combination of the galvanic test of sensory and motor nerves with Roentgen fluoroscopy in the study and diagnosis of diseases of the neuro-muscular system, the nasal accessory sinuses, larynx, thyroid, thymus, lungs, heart, aorta, abdomen and pelvis. His technique is not new but there are novel suggestions in his concurrent use of two familiar modes of examination. [R. M. G.]

A TRANSLATION FROM NICOLAUS CUSANUS.

In the *Annals of Medical History* (Vol. IV, No. 2) VIETS of Boston presents an introductory sketch of Nicolaus of Cusa, followed by a translation of his "De Statibus Experimentis" from the Flach edition in the library of the late Sir William Osler. This treatise on experiments in statistics bears a fundamental relation to medicine; for not only does it present his great achievement of perceiving for the first time the importance of counting the pulse, but it contains significant suggestions on the use of gravimetric methods in the study of blood and urine. It was first published in 1476 as the last of a series of four dialogues between a learned and an ignorant man, following the Socratic pattern. An excellent bibliography and four interesting illustrations complete Viets' valuable paper. [R. M. G.]

CHOLECYSTENTEROSTOMY FROM AN EXPERIMENTAL STANDPOINT.

GATEWOOD and POPPENS, P. H., (*Surg., Gynecol. and Obstet.*, Oct., 1922). These authors write as follows: From the foregoing experiments, performed upon dogs, in which the gall bladder was anastomosed to the stomach, duodenum, and colon, the following conclusions may be drawn:

1. The gall-bladder invariably becomes infected, regardless of the viscous used for anastomosis.
2. There is little, if any, difference between the

stomach and duodenum in the matter of rapidity of infection.

3. The colon is not the portion of the gastro-intestinal tract to be chosen by preference. The immediate dangers of peritonitis are much greater, and probably liver infections would occur earlier than when the upper part of the gut is used.

4. All livers become infected sooner or later if the method employed in our experiments be followed.

5. Cholecystenterostomy, from an experimental standpoint, is not an operation to be recommended for use except in well-selected cases, such as carcinoma of the pancreas, where the temporary comfort of the patient is paramount, or irreparable common duct obstruction. [E. H. R.]

ABSCESS OF THE LUNG.

LOCKWOOD (*Surg., Gynecol. and Obstet.*, Oct., 1922). This author writes as follows:

Contrary to the opinion of the early writers, that abscess of the lung is a common sequela of lobar pneumonia, a survey of the reported cases of the last century would lead us to conclude that it is a rare sequela.

By lowering the resistance in the lung tissue itself, the pneumonias (lobar, broncho and influenza) predispose the patient to the development of lung abscess following pyogenic infection.

Lung abscess occurs more often between the years of 25 and 40. It is three times as common in males as females; it occurs three times as often on the right side as on the left, and about twice as often in the lower lobe as in the upper. Three out of four are peripheral and involve the pleura, and one out of four is multiple.

It must be borne in mind that recently a high percentage of lung abscesses has been the result of neglect or mismanagement on the part of the nose and throat surgeons, the oral surgeons, and the dentists. Such neglect or mismanagement is manifested in the selection of the anaesthetic, and in not keeping the patient's head low, and in not taking sufficient precautions to prevent the patient from inhaling foreign matter. Such a sequela may be avoided by (1) employing a local anaesthetic whenever possible in surgery of the mouth, nose, and throat, and in tooth extraction; (2) keeping the head low during such operations, if a general anaesthetic is employed, until the patient has thoroughly aroused from it; (3) taking care to prevent blood and mucus from accumulating in the throat and being aspirated; and (4) better haemostasis in such work.

The diagnosis depends on the history, the amount, and nature of the sputum, the roentgen-ray, and the physical examination.

A study of results in these cases has led me to conclude that surgery should not be employed as soon as the diagnosis has been made, except as indicated. The mortality has been unnecessarily high in many instances. Instead, thorough medical treatment, with postural rest and drainage, should be instituted. When this fails, pneumothorax should be produced in selected cases, and surgery reserved for those patients who do not respond to the other two methods.

The exploratory needle should not be employed.

When surgery is decided on, paravertebral and local anaesthesia is necessary with gas and oxygen, should be used, and in the majority of cases a more deliberate, extensive, and logical operation should be planned than resection of the chest wall over the abscess, and cavity or blunt puncture of the abscess.

If the patient's condition is such that extensive operation would carry too much risk with it, resection, blunt puncture, and exploration of the abscess with the finger, should be the limit of surgery.

The surgeon, physician and roentgenologist should be intimately associated in the diagnosis and care of these patients. [E. H. R.]

PATHOLOGICAL COMPLICATIONS WITH DUPLICATION OF THE RENAL PELVIS AND URETER (DOUBLE KIDNEY).

BRASCH and SCHOLL, JR. (*Surg., Gynecol. and Obstet.*, Oct., 1922). These authors write as follows:

One hundred and forty patients with duplication of the renal pelvis and ureter have been observed at the Mayo Clinic. The incidence of aberrant and bilateral duplications of ureters and pelvis reported in the literature is relatively too high owing to the tendency to report the more unusual cases. Of the patients in this series the duplication was unilateral in 135 (94 per cent.) and bilateral in 9 (6 per cent.). Of the 135 patients with unilateral duplication, 36 (25 per cent.) had complete duplication, and 99 (68.7 per cent.) had incomplete duplication. Of the 9 patients with bilateral duplications, 8 had complete duplication and 1 had incomplete.

Duplication may vary from duplication confined to the renal pelvis to duplicate pelvis with separate ureters opening into the bladder. The pelvis are generally unequal in size, the upper being the smaller, and are separated by a bridge of normal renal cortex of variable extent. When an unusually small renal pelvis is outlined in the pyelogram, the possibility of duplication should be suspected.

Complete duplication will be discovered more often if a careful search is routinely made for anomaly at the time of cystoscopic inspection. In cases of partial duplication the diagnosis is made only by means of a pyelo-ureterogram.

The lower segment is primarily involved more often than the upper.

Hydronephrosis is the most common pathological complication, and is due to ureteral obstruction, generally in the region of the junction of the two ureters in cases of incomplete duplication.

In tuberculosis of double kidneys, gross evidence of the disease is generally confined to one segment, usually the lower, but in all cases histological examination reveals tubercles in the intervening renal tissue and extending into the remaining segment.

Occasionally when only one pelvis is outlined by the pyelogram, its unusual shape and contour may be misconstrued with pathological changes occurring in single kidneys, such as atrophic pyelonephritis.

In the series of 141 cases, the histories of 19 of which are here reported, 30 patients were treated surgically, 24 patients had definite pathological conditions which did not require surgical treatment, and in 27 evidence of disease was doubtful. Only 61 (42 per cent.) of the patients were without pathological complications, and the anomaly was discovered in the examination for other conditions.

Fifteen of the 30 patients operated on submitted to primary nephrectomies, and 4 to heminephrectomies; 2 of these latter required complete nephrectomy. Six pyelolithotomies and three ureterolithotomies were performed. In one patient hydronephrosis was relieved by the cutting of an aberrant vessel, and in another symptoms were relieved by the ligation of an aberrant ureter from the upper pole of a double kidney.

In the treatment of pathological complications in a double kidney the indication for heminephrectomy is limited to but a few favorable cases. The possibility of infection extending to the remaining half of the rescued kidney, which may necessitate subsequent complete nephrectomy, must be considered.

[E. H. R.]

THE DYSTOCHIAS OF THE HEART, WITH REPORT OF CASE.

LEWIS, (*Surg., Gynecol. and Obstet.*, Oct., 1922). This is a most interesting case, which on post-mortem examination showed a well developed hydatid cyst of the middle of the heart. The author has presented a most interesting review of the literature on this subject and bibliography. These cases are

extremely unusual, and diagnosis has never been made before autopsy. Death has usually been sudden and unexplained on the usual pathological grounds except in cases where hydatid cyst has been known to exist in other parts of the body. [E. H. R.]

BONE FORMATION IN OPERATIVE WOUND CICATRICES.

JONES (*Annals of Surg.*, Oct., 1922) reports a unique case in which an operation for inguinal hernia was followed by definite bone formation in the scar. There was no history of infection. The new bone was not connected with muscle in any way, but lay in the scar tissue and was freely movable. It was not attached to the pubic bone, and it was easily separated from the connective tissue which extended through the little holes in the specimen. Histological examination showed the specimen to be true bone, no cartilage or connective cells were found.

The author explains the formation of it by stating that the operator, in placing his last suture, pricked the pubic bone with the needle, and carried some of the osteogenic cells into the wound, where they later proliferated.

The condition suggests the possibility of growing osseous tissue outside of the body. [E. H. R.]

INTUSSUSCEPTION OF STOMA FOLLOWING GASTRO-ENTEROSTOMY.

LEWISOLIN (*Annals of Surg.*, Oct., 1922) reports an extremely interesting case in which intussusception occurred at the site of a gastro-enterostomy opening with symptoms of acute intestinal obstruction. The author furnishes an excellent drawing of this case. [E. H. R.]

PERIPHERAL NERVE INJURIES ASSOCIATED WITH FRACTURES.

LEWIS and MILLER (*Annals of Surg.*, Oct., 1922). These authors write as follows:

Nerve injuries are associated with fractures much more frequently than supposed. They are frequently overlooked because of the hasty and incomplete examination of fractures. When fractures are examined the possibility of a nerve injury should always be kept in mind.

The character of the injury varies greatly, from the slightest contusion from which the patient rapidly recovers, to anatomic division and callus inclusion, which demand surgical interference.

It is often impossible to differentiate by the most careful neurological examination between physiologic interruption of the nerve current and anatomic division of the nerve.

There is a tendency in these cases to wait too long for spontaneous recovery.

When recovery has not commenced within three months after the injury, the injured nerve should be explored and the surgical procedures demanded by the pathological findings be instituted.

Neurolysis is the operation which will be most frequently required. Resection of the humerus should no longer be resorted to to permit of end-to-end suture of the musculospiral nerve. Tendon transplantation should be performed in these cases.

The prognosis is very favorable in injuries of this type because of the frequency with which the musculospiral nerve is the one injured, and because of the relative infrequency with which it is divided, only neurolysis being necessary.

In the late ulnar nerve palsy, transposition of the nerve to the front of the elbow will be necessary in the cases of cubitus valgus. When bony outgrowths cause the paralysis, removal of such outgrowths and the placing of the nerve in a healthy bed may be all that is required. [E. H. R.]

THE SURGICAL RELIEF OF INTENSIVE TORT OF INFLAMMATION IN CASES OF ARTERIAL PLETHORASMS

SMITH, R. (*Annals of Surgery*, October, 1922). This author writes as follows:

We believe that we have clinical proof that chronic polyarthritides is the result of a focal infection located in the ileocecal coil. That no study of a case of arthritis is complete without a careful investigation of the gastro-intestinal tract, especially of the ileocecal coil, for both motility and mobility. In the event that a pocket exists in the intestine, the rational procedure is first an abdominal operation to straighten out bad mechanics and restore function to the caecum, a prolonged medical regime to restore the unbalanced intestinal flora to normal and then such orthopedic procedures as are necessary to restore function to damaged joints. [E. H. R.]

TREATMENT OF CARCINOMA OF THE RECTUM.

COFFEY, R. C. (*Annals of Surgery*, October, 1922), presents, in the writer's opinion, the best article on the operative treatment of cancer of the rectum recently published. His diagrams so well explain the text that it is almost unnecessary to read his text, except to emphasize certain important steps. The logic of his operative procedure is easily seen. The article is of extreme value. [E. H. R.]

A BACTERIOLOGIC STUDY OF THE FLUID CONTENTS OF 100 GALL-BLADDERS REMOVED AT OPERATION.

DRENNAN, J. G. (*Annals of Surgery*, October, 1922). This author writes as follows:

In a series of 100 gall-bladders removed at operation only 19 per cent. contained fluid infected with bacteria; the infecting organisms were bacillus coli in 12 per cent. of the cases, a staphylococcus in 4 per cent., a streptococcus in 2 per cent., and a non-pigment-forming sarcina in 1 per cent.

The probable reason there is not a higher percentage of infected gall-bladder fluids is that the contained fluids have a concentration of bile too high, for bacteria will not grow satisfactorily if more than 70 per cent. of bile is present.

In the 19 per cent. of infected gall-bladder fluids the concentration of the normal bile had been lowered by inflammatory exudates, thus permitting the growth of bacteria in the fluid contents of the gall-bladders. [E. H. R.]

THE SURGICAL TREATMENT OF SYPHILIS OF THE STOMACH.

GRAHAM, E. A. (*Annals of Surgery*, October, 1922), contributes a valuable paper on this subject, giving a very accurate description of the lesions, and reports three cases in detail. He states in conclusion that surgical complications of gastric syphilis occur with probably greater frequency than is commonly recognized. These consist usually of deformities produced by scar tissue formation in the healing of the syphilitic process. They are commonly seen, therefore, as stenoses at or near the pylorus, but sometimes as hour-glass contractures or perigastric adhesions. In another group in which there is impaired motility without organic stenosis of the pyloric orifice but with rather generalized sclerosis of the whole stomach, it is doubtful how much good, if any, can be accomplished by surgical measures. In a study of thirty-four cases (including thirty-two from the literature and two from the author's series) resection of the pylorus gave uniformly good results in cases of stenosis of that orifice, while gastroenterostomy was frequently followed by only slight or temporary

improvement. It would seem, therefore, that pylorotomy is more likely to be followed by complete relief of symptoms than is simple gastroenterostomy, although a study of more cases may show that the latter operation is sufficient in cases of actual stenosis of the pylorus. There will remain certain cases without organic obstruction in which surgical measures will probably not be indicated. [E. H. R.]

CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORI IN THE ADULT.

OLIVER, J. C. (*Annals of Surgery*, October, 1922), very briefly discusses the literature so far appearing on this subject. This literature is extremely meagre, only a very few cases having previously been reported. The author reports in detail a case in which the diagnosis and operation are described. The Rammstedt was employed with complete relief. [E. H. R.]

THYROID SURGERY AND THE DEMENTIA PRAECOX SYNDROME.

EASTMAN and EASTMAN (*Annals of Surgery*, October, 1922).

These authors call attention to the frequency of thyroid disease and dementia praecox occurring in the same patient, and give full histories of four cases in which leuhotomy was done for relief of the nervous symptoms. They discuss various theories in regard to the intra-relationship of these two conditions, but do not attempt to entirely explain it, and they conclude from their observations that there seems to be a reasonable expectancy that the partial removal of the thyroid will in certain cases relieve the symptoms of dementia praecox. The article is suggestive. [E. H. R.]

THE CHOICE OF OPERATION FOR GASTRIC ULCER IN VIEW OF THE LATE RESULTS.

WOOLSEY, G. (*Annals of Surgery*, October, 1922), writes as follows:

For ulcers three to four or more inches from the pylorus, the choice lies between excision and meso-gastric resection. On account of the better results I prefer excision and gastroenterostomy, except for ulcers with hour-glass contraction and large indurated ulcers, especially those on the posterior surface.

For ulcers near the pylorus, or within three inches or so of it, I prefer the Polya method. It is easy, reasonably rapid and has given the best results of any method.

In case the operation is done in two stages, or a gastroenterostomy has previously been done, the Billroth II method is the rational procedure, but the two-stage procedure is rarely called for in cases of ulcer.

For ulcers at, or close to, the pylorus, especially such as cause a stenosis, a posterior gastroenterostomy is the simplest and safest operation, gives good results and may be the method of election for those not experienced in resection. It is quite possible for such an operation to benefit or cure ulcers remote from the pylorus.

The possibility of cancerous degeneration of a gastric ulcer would in general lead to its resection or excision, but, as was long ago pointed out by Kocher and others, such degeneration is quite uncommon in cases treated by gastroenterostomy. In view, however, of this danger, whether we class it at a high per cent. with some or a low per cent. with others, I firmly believe in the complete removal of gastric ulcers by resection or excision unless the operative risk is greatly increased on account of the general or local condition of the patient. [E. H. R.]

X-RAY AND CLINICAL FINDINGS IN NORMAL CHEST OF CHILDREN SIX TO TEN YEARS.

The National Tuberculosis Association Medical Research (*Canad. M. A. J.*, vol. xii, No. 8, Aug., 1922) reports their findings in over 500 children with no chest abnormalities. Their findings are presented as follows: clinically, the ideal, normal child is a hypothetical impossibility. Children, apparently healthy, symptom-free and active, show on careful examination many deviations from fixed standards, variations that must be interpreted as within physiological limits; standards of height and weight must be elastic, measures of resonance and resilience of the chest must not be rigid, and estimates of acoustic phenomena must permit of a range of difference from the ideal. These facts, clinical experience establishes beyond peradventure, and they suggest a corollary, namely, that x-ray examination of the chest of such children may be expected to show comparable deviations from a fixed ideal roentgenogram. Inasmuch as the changes referred to are dependent often upon alterations that persist as the residua of past infections of the respiratory tract, it is obvious that a careful anamnesis, with special reference to all infections, is necessary if diagnostic errors are to be avoided. Even a history carefully taken is often unreliable, as minimal infections are soon forgotten by many, and among the unintelligent classes even more significant indispositions are not readily recalled. Failure properly to evaluate these deviations from a fixed standard will often lead to the unwarranted diagnosis of disease and to even less justifiable treatment. With a proper appreciation of the widest variations that the normal may present from the ideal, the informed clinician is better able correctly to understand the findings of the roentgenologist, and each, coöperating with the other, is less liable to error. D'Espine's sign as indicative of enlarged tracheo-bronchial lymph nodes is of little value. Recognition of and familiarity with the foregoing data are of cardinal and practical importance to every patient, potential and established. Without a proper appreciation of the facts set forth, no intelligent differentiation between a normal and an abnormal respiratory tract can be made. The normal chest of the child from the roentgenologic standpoint is subject to such wide variations within normal limits as to be beyond the possibility of description. The conglomerate shadow commonly called the hilum shadow, when found lying entirely within the inner third or zone of the lung area, can be disregarded (or regarded as normal), except where it is made up of a solid mass of homogeneous shadow giving undoubted evidence that it represents a growth or mediastinal pleurisy. Calcified nodes at the root of the lung, without evidence of lung disease, are of no significance except as a possible evidence of some healed inflammatory condition, possibly but not necessarily tuberculous. They are a common finding in normal chests. In brief, to establish the presence or absence of disease, it is imperative that all data—clinical, laboratory, and roentgenographic—must be evaluated and correlated and that no one fraction of the evidence be stressed to the exclusion of the others.

THE EFFECTS OF ULTRAVIOLET RAYS ON THE CALCIUM AND INORGANIC PHOSPHATE CONTENT OF THE BLOOD SERUM OF RACHITIC INFANTS.

TISDALE, F. E. (*Canad. M. A. J.*, vol. xii, No. 8, August, 1922), uses the following technique: he started with exposures of 5 minutes' duration with the lamp 100 cm. from the body, in the case of small infants. The length of exposure was gradually increased and the lamp moved nearer the body until a maximum exposure was given of 15 minutes' duration at 60 cm. He finds that exposure of rachitic infants to ultraviolet rays from a mercury vapor quartz lamp, for

very short periods, caused a marked increase in both the calcium and inorganic phosphate content of the blood serum, which was followed by clinical and roentgenographic evidences of healing. No increase in the serum calcium and inorganic phosphates was obtained by prolonged exposure to the rays from an ordinary 500-watt incandescent lamp.

POST-OPERATIVE COMPLICATIONS OF THE RESPIRATORY TRACT.

DECKER, H. R. (*Canad. M. A. J.*, vol. xii, No. 8, August, 1922), found that those with history or evidence of recent acute respiratory inflammation, those with chronic lesions, as bronchitis or emphysema, those with pulmonary hypostasis, whether cardio-renal, or due to cachexia of old age, are poor respiratory tract risks. He carries out the following prophylactic régime: before operation—careful history and physical examination are done in order to find cases of the above types; careful nursing rules are carried out—a 70° temperature in bathrooms is maintained; the patients are kept warm and out of drafts; the anaesthetic is carefully chosen, replacing ether in many cases by spinal or rectal anaesthesia; oral hygiene is insisted upon; during operation—careful precautions are taken against chilling; the anaesthetic is given only by one especially trained for it; surgical technic is designed to eliminate the etiologic factors of thrombo-embolism, as suggested by Ochsner; dressings are applied firmly, but so as not to impede respiration, abdominal binders not being often used; after operation—exposure is carefully avoided, free movement in bed is encouraged, and raising of the head and thorax from the flat position is encouraged, especially if hypostasis is present.

FEAR, A HARMFUL EMOTION—HOW MAY WE ELIMINATE IT FROM THE SURGICAL PATIENT'S MIND?

GUTHRIE, DONALD (*Canad. M. A. J.*, vol. xii, No. 8, August, 1922), suggests the following points to be carefully considered in a surgical hospital in order to minimize the patients' fears: the doorman, telephone girl, clerks, etc., at the entrance, must be of a cordial type; the patient must not be kept waiting in the ward to watch the hurrying about while she seems to be neglected; the admission should be to a convalescent ward, not to one where is suffering; there should be as little delay as possible before operating; the surgeon should personally talk the case over the night before and encourage the patient; sound sleep should be provided, not a night of trips to the bathroom; operations should be done as early in the day as possible; the anaesthetist should be most carefully chosen, and silence should be preserved by all about except the anaesthetist, and rattling and bustling about should not be permitted; recovery should be in a quiet room, morphia should be given freely, and an abundance of water; before discharge, the patient should be told in detail what the operation was, what the after-care should be, and encouraged to report progress from time to time after returning to the patient's home physician.

REPORT OF A CASE OF BROMIDE ERUPTION IN A NURSING INFANT.

BOONE, F. H. (*Canad. M. A. J.*, vol. xii, No. 8, August, 1922), reports a case of a six months' old infant that received sufficient bromide through the mother's milk to produce marked cutaneous signs of bromide poisoning. The mother was receiving 45 grains of sodium bromide a day, for seven and a half weeks. The first symptom in the baby began four and a half weeks after the mother began taking the drug. The mother never developed any symptoms. After discontinuance of the drug, the baby steadily improved.

BONE SUPPURATION: THE BASIC CAUSE OF RENAL CALCULI IN TWENTY CASES FOLLOWING WAR WOUNDS.

PAUL, H. E. (*Canad. M. A. J.*, vol. xii, No. 9, September, 1922), presents a discussion of the previous writings on the subject and the findings in twenty of his cases in ex-soldiers. The oldest was 37, the youngest 22; with one possible exception there appeared to be a definite history of bone suppuration in all. Urine from 18 of these cases showed well marked evidence of infection; one case was constantly free from organisms by the microscope, the other was so on the affected side by culture. Staphylococci were the commonest; colon bacilli occurred. Lack of drainage in the upper urinary tract seems not to be an important primary cause of the formation of renal calculi following such a systemic infection as bone suppuration.

MESENTERIC THROMBOSIS—WITH REPORT OF TWO CASES.

PARKER, C. B. (*Canad. M. A. J.*, vol. xii, No. 9, September, 1922), reports in detail two cases, one with operation and recovery, the other with operation and autopsy; he describes the cases in detail.

A STUDY OF 443 CASES OF HEREDITARY SYPHILIS WITH ESPECIAL REFERENCE TO RESULTS OF TREATMENT.

WHITE, P. J., and VEEDER, B., of St. Louis (*A. J. Syphilis*, vol. vi, No. 3, July, 1922), report their investigation of 396 families containing 443 definitely congenital syphilis who were treated and watched with adequate hospital, clinic, and social service facilities; 197 were under two years of age, the other 246 children were first seen when in the stage of "late" congenital syphilis. They discuss some of the literature on congenital syphilis by previous authors.

From the social standpoint, they found the group difficult to deal with on account of lack of interest on the parents' part, only 52 parents out of 230 helping to follow out a thorough course of treatment, while 95 were absolutely uncooperative. In spite of careful and intensive follow-up work, only about one-third of the cases were brought back long enough to have adequate treatment. From the medical point of view, they found that the individual case has a fair chance of clinical and serological recovery or improvement, occasionally with fairly little treatment, much better with thorough treatment with the arsenicals and mercury; if serological and clinical evidence of central nervous system involvement is present, the chances of recovery or real improvement are poor. As regards the group as a whole, they find the results disappointing; even in spite of treatment, the infant mortality rate was three times that for other infants of the same age limits in the same city (St. Louis). Approximately one-third of the group had involvement of the central nervous system, and showed very little improvement; the residue left usually placing the child among the socially unfit. The authors group as follows the 308 cases whose end-results are known: cured or recovered, 22%; improved, 35%; unimproved, 17%; died, 25%. They advise as the greatest help to the problem that the syphilitic mothers be treated so far as possible both to prevent the children from being syphilitic, and also to cut down the large number of syphilitic foetal deaths, as prevention is much more satisfactory than cure.

THE DIAGNOSIS OF EARLY SYPHILIS.

STOKES, J. H., and McFARLAND, A. K. (*A. J. Syphilis*, vol. vi, No. 3, July, 1922), analyze 231 cases of primary and secondary syphilis, largely untreated. They emphasize the fact that the primary lesion should be diagnosed not by clinical criteria, but by the dark field microscope and the Wassermann test. They found that 55.65% of all genital lesions were

proved at the first examination to be chancres of syphilis, 88% of the primary lesions gave positive dark fields the first week, 66% were positive regardless of age, while none were positive by the ninth week. 70% of the Wassermann tests made during the second week of the primary were positive, thus showing that each test is at its best when the other is the least useful. No local applications whatever should be applied to the lesion until the dark field examination has been repeatedly made, yet 11 out of 17 cases gave positive results, including one that had been cauterized and three that had had a little arsphenamin and mercury. Aspiration of the satellite bubo yielded 50% positive dark fields. Of 80 patients who had been previously examined, only three had had a dark field examination made. "Chancroid" should never be diagnosed within four months of the appearance of the lesion under suspicion, until the possible presence of syphilis has been absolutely excluded. All genital lesions (the reviewer would add, all lip lesions) should be considered chancres until proved to be otherwise. One man had been used as a transfusion donor while his chancre was present, and 10 days before the secondary eruption appeared, when he should have been at the height of his spirochetemia. In the secondary moist lesions, 23 out of 24 dark field examinations were positive. In this series, 24% of the patients with well developed secondary syphilis, a high percentage, could give no history of any chancre, including one physician; this number includes women, who are apt to show no primary. 75% of the women, 64% of the men, had infectious lesions when first seen. A half of the group had constitutional symptoms with the secondary lesions, only 4 in 28 in the pre-eruptive stage; the women showed a greater percentage than the men, 63% as against 43%; the leading symptoms were sore throat, headache, and head pain. Combinations of mild fever, sweats, loss of weight, asthenia, gastrointestinal symptoms, nervous irritability, arthritis and myalgic pains, and anaemia, are frequent and are easily confused with early tuberculosis; they justify a routine Wassermann test in suspected tuberculosis, especially in early adult and middle life.

AN ARSPHENAMIN DERIVATIVE SUITABLE FOR SUBCUTANEOUS ADMINISTRATION.

VOEGTLIN, DYER, and THOMPSON, of the Division of Pharmacology, Hygienic Laboratory, U. S. P. H. Service, describe in detail their experimental work on an arsphenamin derivative, prepared from arsphenamin, formaldehyde, and sodium sulphite, which began to be made in 1919 by the Laboratoire de Biochimie Medicale in Paris, hoping to stimulate others to try it out. It closely resembles nearsphenamin chemically and in appearance, but is very stable in watery solution in the presence of air. It gives no local irritation following subcutaneous injection. It has been tried out by several clinicians in a small number of cases, not enough yet so that its therapeutic dose has been determined, though probably doses slightly larger than those of nearsphenamin can be used. The toxicity is about the same as the average nearsphenamin, while the trypanocidal power is slightly less. The excretion rate of the arsenic in the drug is about the same as in arsphenamin and nearsphenamin.

THE WASSERMANN REACTION FROM THE CLINICIAN'S POINT OF VIEW.

BOEWMAN, C. J. (*A. J. Syphilis*, vol. vi, No. 3, July, 1922), discusses 1742 Wassermann tests made on 365 private cases, giving in chart form the Wassermann reports from three laboratories, the diagnosis, and in many cases notes as to the exact symptoms, amount of treatment, etc. He emphasizes the importance of careful clinical examination and history, especially in view of the fact that this series showed a discrepancy

of some sort in 36% of the cases, 52 cases with definite syphilis had negative Wassermann tests in at least one laboratory. A clean cut case of syphilis needs no Wassermann, but one should always take one to prevent subsequent criticism by the patient or another physician. A negative Wassermann is of no value in the presence of a penile lesion. A diagnosis of syphilis on one positive Wassermann, especially a weakly positive, cannot be too strongly condemned, but must be checked up by clinical findings or several tests in more than one laboratory. An early negative Wassermann in the course of treatment is encouraging, but does not mean cure by any means, as a varying per cent. of cases of very definite syphilis have negative Wassermann tests. The author emphasizes the need of a more standardized technic of the Wassermann reaction, and a need of the serologists to realize more their responsibility in reporting Wassermanns.

THE DISTRIBUTION AND EXCRETION OF ARSENIC AFTER INTRAVENOUS ADMINISTRATION OF ARSPHENAMIN IN CHILDREN.

CLAUSEN, S. W., and JEANS, P. C. (*A. J. Syphilis*, vol. vi, No. 3, July, 1922), studied a group of children under treatment for syphilis to determine the excretion of the arsenic, and studied the distribution in the body on kittens. They gave to the children in all cases a dosage of 10 mg. per kilo of body weight. Blood was taken at intervals of 2, 10, 20, and 30 minutes, and 1, 3, 6, and 24 hours after the injection. They describe in detail their method of arsenic determination, and give tables and graphs showing their results, which they summarize as follows: Arspheamin rapidly disappears from the blood, but 10% remaining in one hour. In the blood it is present exclusively in the plasma. The organs taking up the largest amounts are the liver and small and large intestines. The excretion begins immediately, is very rapid at first, gradually diminishing until at the end of two weeks only traces are found. However, at the end of two or even three weeks 50% is still in store in the tissues. It is excreted five times as rapidly in the stools as in the urine. The curve of excretion by the urine is a peculiar one and is evidently a composite of two curves. It seems likely that the curve of excretion via the stools would be of the same type if the stools should be collected accurately at stated intervals. The amount of arsenic found in the cerebro-spinal fluid is greatest in the first hour (in some cases two hours) after intravenous administration. The amount of arsenic found in the cerebro-spinal fluid seems to depend upon the amount of inflammation present. In some children with no evidence of neuro-syphilis no arsenic is found. The greatest amounts were found in those cases with evidence of the most active inflammation. More was found in infants with neuro-syphilis than in older children similarly affected. In all patients was noted a diminishing amount of arsenic in the cerebro-spinal fluid at succeeding injections and for the same time intervals. The arsenic content of the spinal fluid is at least as great in cases of cerebro-spinal syphilis after intravenous administration of arspheamin as would result from the intrathecal injection of arspheaminized serum according to the Swift-Ellis technic.

CARCINOMA OF THE TONGUE AND ITS TREATMENT WITH RADIUM.

TAUSSIG, LAWRENCE (*Arch. of Derm. and Syphil.*, vol. vi, No. 1, October, 1922). A carcinoma, leukoplakia, and chronic syphilitic glossitis may all predispose to cancer, though the determining factor in the change is obscure. In the non-syphilitic cancer of the tongue may be caused by the excessive use of tobacco, or may start in a chronic ulcer caused by a rough tooth,

though in many, no previous lesions seem to have been present. The author has treated during the last two and a half years 11 patients with cancer of the tongue; two were women, the ages varied from 36 to 63; 4 had syphilis as well; 2 are clinically well two and a half years after radium treatment, one after one and a half years, one at six months, 5 showed metastasis at time of treatment and all died, 5 others have died. The author believes that with improved technic 25% of unselected cases of cancer of the tongue can be cured with radium.

CANCER OF THE LIP TREATED BY ELECTRO-CAUTERIZATION AND RADIATION.

PEABLER, G. E. (*Arch. of Derm. and Syphil.*, vol. vi, No. 4, October, 1922), states that no form of treatment will cure late cases, so early and thorough treatment is necessary, always by radiation, often by other means as well; while all irritations of the lip should be looked upon as either malignant or syphilitic if lasting over a month. 105 private cases were treated, 80 primary, 20 recurrent, and 5 post-operative. Of the 80 primary cases 74 recovered and have been well for from several months to 18 years, 2 died of a continuation of the disease, two had recurrences, the outcome of one is not known. Radiation should be used thoroughly in all cases. If surgery or electro-cauterization is to be used also, a preliminary radiation with a full erythema dose should be given over the lip and chin, submental and submaxillary regions, and repeated two to three weeks later, after the operation. Metastatic lymph nodes should be treated by surface radiation followed by excision or by radium implantation.

TREATMENT OF CANCER OF THE LIP BY RADIATION.

LAIN, E. S. (*Arch. of Derm. and Syphil.*, vol. vi, No. 4, October, 1922). The cellular morphology of cancer of the lip has less importance in the prognosis than the location or degree of development or the age of the patient. He has repeatedly observed that on account of a beginning atrophy of the lymph system, after a certain age the prognosis is bad. Especially is this true of cancer of the lower lip. We believe that a prickle or a squamous cell cancer, in the early stage of its growth, will undergo degenerative changes under radiation from either radium or roentgen ray just as the basal cell variety does. They differ only in the amount of radiation necessary and the technic of its application.

Finally he believes that sufficient statistics, verified both by clinical and laboratory findings, have now accumulated to justify the conclusion that cancer of the lip is equally and perhaps more amenable to treatment by roentgen ray or radium than by surgery, and in most cases radiotherapy is to be preferred.

YAWS: ITS MANIFESTATIONS AND TREATMENT BY NEO-ARSPHENAMIN.

GUTIERREZ, P. D. (*Arch. of Derm. and Syphil.*, vol. vi, No. 3, September, 1922), discusses 275 cases of yaws treated near Manila. He states that in this locality at least the disease is confined largely to the poor and to the coast towns; the disease is transmitted by direct contact, usually in childhood and adolescence, and scabies seems to be a factor in the transmission of the disease. The disease has three stages—the primary, the secondary, and the tertiary. The primary has an incubation period of from two to four weeks, develops usually on the exposed surfaces, starts as a papule, becomes moist after a week, a crust soon forms and an ulcer develops under the crust. This lesion is usually painful, and the neighboring glands are swollen. The primary lesion may heal before the secondary eruption appears, or may

last for many months or some years, longer even than the secondary lesions in the same patient. The secondary lesions seem to appear from one to three months from the beginning of the primary, and are preceded by malaise, fever, and bone and joint pains. The secondary lesions may occur in successive crops, each taking from three months to a year to clear up. Most of them take one of the following types: nodular or framboesiform, papular, or mucular. The secondary and tertiary lesions frequently intermingle, occasionally the primary also. The tertiary lesions are largely of the following types: chronic periostitis of the long bones, painful and disabling; gummata, frequently closely resembling syphilitic gummata; keratosis, especially of the palms and soles. Yaws is much more sensitive to arsenphenamin than is syphilis.

THE SIGNS OF FILARIAL DISEASE.

R. BLACKLOCK (*Annals of Tropical Medicine and Parasitology*, vol. xiv, No. 2, July, 1922).

It is generally believed that "tropical elephantiasis" results from filarial infection, but that "sporadic elephantiasis" such as occurs in temperate climates is in no way dependent on the presence of the filaria. Blacklock's findings based on the examination of 240 cases seen in or near Sierra Leone lead him to the conclusion that "many of the signs of filarial disease" have no more correlation with the presence of microfilaria in the blood than has hernia; some have less. Accepted views regarding the rôle played by the filaria in elephantiasis may perhaps require revision.

[G. C. S.]

THE BLOOD SERUM IN PERNICIOUS ANEMIA.

BROCKBANK, E. M. (*British Medical Journal*, July 22, 1922), presents the following conclusions as a result of his observations on the blood serum in pernicious anaemia:

1. The serum of pernicious anaemia is always definitely yellow and that of all other anaemias nearly colorless. The color may be seen in two or three drops of serum in a small glass bulb.

2. Oxyhaemoglobin absorption bands appear in the serum of the great majority of cases of pernicious anaemia, and can easily be seen by a pocket spectroscope. They are not seen in the serum of other anaemias.

3. Continental observers have found haematin in the serum of some cases of pernicious anaemia, and they believe that bilirubin gives rise to the yellow color.

4. There may be some free oxyhaemoglobin in the plasma of the circulating blood of the disease.

5. It is possible, judging from the serum, that there are at least two varieties of the disease.

6. Blood plates are generally very scanty or absent in the disease, but when present are a sign of potential regeneration of red cells by the bone marrow and indicate a good temporary prognosis.

7. The abnormal conditions of the red corpuscles suggest the possibility of pernicious anaemia being a malignant disease of the blood.

[J. B. H.]

SOME ASPECTS OF CARDIAC DISEASE.

HAY, JOHN (*British Medical Journal*, July 22, 1922), discussing cardiac disease, summarizes his remarks as follows:

Irregular action of the heart is not merely a matter of degree. The types differ fundamentally and their significance varies widely.

The most important group is that of the flutter of the auricle, characterized by a special and fundamental change in the activity of the auricles, and a frequent and disorderly action of the ventricles.

This increases the load of the heart and is the most common cause of cardiac failure. The recognition of this form of irregularity is not difficult, requiring only the fingers and a trained intelligence.

Fibrillation is not confined to any one particular form of cardiac lesion, but may occur at any age, and when once established tends to persist.

The digitalis group produces a remarkable slowing of the ventricular rate with consequent improvement in the patient.

Auricular fibrillation can in 50 per cent. of the cases be terminated by quinidine sulphate, but in many patients the fibrillation recurs, and the exhibition of this drug is not without danger.

[J. B. H.]

COLLIS, HINDHED, BALLANTYNE, STOCKARD and others (*British Medical Journal*, August 12, 1922) continue the discussion of alcohol and its relation to social problems.

Collis considers alcohol and industrial efficiency, the effect of convivial drinking and of industrial drinking. Considering the industrial and experimental evidence in regard to the subject, although alcohol possesses a charm for removing the irritating effects of industrial fatigue it is a charm purchased at great cost to efficiency. The evidence drawn from American sources as to the beneficial effect upon industrial efficiency of prohibition when taken as a whole can hardly be controverted, even though it may be criticized piecemeal. He summarizes his remarks as follows:

1. Alcohol is a drug possessing energy which the body can use, but probably not for muscular work.

2. Alcohol interferes adversely with reflex acts and neuro-muscular co-ordination. The higher the concentration in which it is consumed the more pronounced is the effect.

3. Alcoholic habits vary with industries, and where most pronounced time-keeping is most irregular.

4. Industrial accidents are increased by the consumption of alcohol even though in moderate amounts.

5. There is no evidence, either experimental or practical, that alcohol is advantageous to industrial efficiency, and much that it is harmful.

6. Prohibition in America appears to be associated with greatly improved industrial efficiency, whether measured by accident frequency, lost time, or output.

Hindhede considers alcohol restriction and mortality; Ballentyne takes it up with relation to infantile mortality.

Stockard considers the subject as a selective agent in the improvement of racial stock.

[J. B. H.]

THE BACTERIOLOGY OF INFLUENZA.

GORDON, MCINTOSH, and others (*British Medical Journal*, August 19, 1922) discuss the bacteriology of influenza. McIntosh concludes his remarks as follows:

1. The predominating micro-organism in the secretions and lesions of the late epidemic was *B. influenzae* (Pfeiffer), which could be demonstrated in from 75 to 80 per cent. of the cases.

2. Other members of the catarrh-producing group of bacteria (pneumococci, streptococci, *M. catarrhalis*, etc.) were much less frequent.

3. Serological examinations confirmed an infection by *B. influenzae*.

4. The possibility of producing, experimentally, influenza-like lesions in the respiratory tract and lungs with filtered cultures of *B. influenzae* was demonstrated.

5. No evidence was obtained in support of the view that influenza is due to a filter-passing virus.

[J. B. H.]

THE BOSTON Medical and Surgical Journal

Established in 1828

Published by The Massachusetts Medical Society under the jurisdiction of the following-named committee:

For three years WILLIAM H. ROBEY, JR., M.D.,
ROGER I. LEE, M.D.,
ROBERT B. OSWOLD, M.D.
For two years JAMES S. STONE, M.D.,
HORACE D. ARNOLD, M.D.,
CHANNING FROTHINGHAM, M.D.
For one year HOMER GAGE, M.D., Chairman,
EDWARD C. STREETER, M.D.,
EDWARD W. TAYLOR, M.D.

EDITORIAL STAFF.

WALTER P. BOWERS, M.D., *Managing Editor*.
GEORGE G. SMITH, M.D., *Assistant Editor*.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

THE AMERICAN SOCIETY OF CLINICAL PATHOLOGISTS.

THE organization of "The American Society of Clinical Pathologists" was accomplished in St. Louis in May, 22 and 23, 1922. The proceedings of this first meeting, containing the discussion preliminary to organization, and the constitution and by-laws adopted, stimulate reflections upon the status of those engaged in the practice of an important and essential part of medicine, as well as the use and abuse of the pathologist by physicians and surgeons. The objects of the Society are stated to be:

"(a) To promote the practice of scientific medicine by a wider application of clinical laboratory methods to the diagnosis of disease; (b) to stimulate original research in all branches of clinical laboratory work; (c) to establish from time to time uniform standards for the performance of various laboratory examinations; (d) to elevate the scientific and professional status of those specializing in this branch of medicine; (e) to encourage a closer coöperation between the practitioner and the clinical pathologist."

The Code of Ethics, in the by-laws, is as follows:

"Section 1. The Code of Ethics of this

society shall be the same as that of the American Medical Association.

"Section 2.—It is deemed unethical to publish advertisements in medical journals calling attention to the merits of a particular laboratory or announcing the fees for laboratory examinations.

"Section 3.—It shall be deemed unethical for a member of the society to lend his name for publication in the laboratory advertisements violating this Code of Ethics."

The discussion which preceded the creation of this society clearly indicates that the chief incentive to organize was dissatisfaction with the prevailing status and financial returns of the practice of clinical pathology.

If the practice of clinical pathology is a branch of medicine, no other branch is so thoroughly commercialized.

The discussion calls attention to the firms with offices in many cities, advertising their proficiency and their fees and rejoicing in the sponsorship of eminent professors of laboratory subjects in some of our best universities. Attention is also called to the prevailing regard on the part of "clinicians" of the clinical pathologist as a technician.

For our part, we believe that the major part of the work done in clinical pathological laboratories is technicians' work, just as it has come to be so in many of our large hospitals. Wassermann reactions, metabolism tests, quantitative urine and blood analyses, in fact any diagnostic procedure removed from the patient that may be accomplished by quantitative methods may be relegated to well-trained non-medical workers. However, the interpretation of the result as applied to the patient is made not by the house-officer, but by some one higher in the medical staff, and often by the chief of service.

In the interpretation of the laboratory procedure lies the crux of the situation. The clinical pathologist, that is, the person who delivers reports on specimens of tissue, blood, urine, feces and cerebro-spinal fluid, rises above the status of technician only when such reports involve interpretation. The diagnosis of a microscopic preparation made from tissues, the diagnosis of fluoroscopic studies of stomach or intestines, from x-ray plates of bones, and some bacteriological procedures, can only reliably be made by persons of extensive experience and wide knowledge of possibilities. These and possibly a few other laboratory procedures belong to the expert whose services should be recognized by fees and esteem as are those of any other consultant. As consultants, the pathologist, the roentgenologist and the bacteriologist should be prepared to assume, and as a matter of fact are accustomed to assuming, the respon-

sibilities of authorizing important medical and surgical procedures for which services the patient should be as willing to pay as he is to pay for the opinions of men whose data are obtained by stethoscope, ophthalmoscope, bronchoscope, speculum or any other time-honored method.

To the laboratory man, holding a university position, the practitioner sometimes appears in the light of the middle man in commerce, for not only does the practitioner profit by the application of discoveries made in laboratories, but he also conceals from the patient the importance of expert services on the part of the pathologist enlisted for help in diagnosis. Another practitioner called in consultation expects and receives a consultant's fee, the pathologist is grudgingly conceded a small fee, in amount, in most parts of the country, determined by the charges of the commercial laboratories.

The laboratory worker has made modern medicine and surgery possible—where would surgery be without asepsis?—and like scientific men in general "He digs for others and then begs for a bit of the gold he has dug" (See Cattell, "The Organization of Scientific Men" in *The Scientific Monthly*, June, 1922).

Scientific workers as a whole are content to labor because of love for the work, since the road from discovery to financial return is a long one and not apparent or attractive. However, the pathologist who does not desire to practice is constantly being forced to turn away from his research pursuits in order to give assistance in diagnosis, and after time-consuming work often has occasion to reflect on the meagerness of his reward, in appreciation and with money, as compared to that of a clinical consultant.

The pathologist lives close to the practitioner; that he is necessary is evidenced by the free laboratory services supported by the State. The beginner in pathology quickly learns what lies ahead for him in academic or hospital work. He sees that nearly every pathologist has to do a large amount of routine in hospital or medical school, and much free work for charity patients in order to earn his salary and privilege of engaging in research. The anatomist, the physiologist, the pharmacologist, has his teaching and research. The pathologist has in addition routine and charity work. The beginner in pathology quickly realizes also that he may pursue most lines of pathological research in laboratories of medicine or surgery and for a period of years thus straddle the fence dividing laboratory from clinical career, or finally engage in practice with financial concern in place of routine, while carrying on investigation. These are some of the reasons why so few able men are now entering pathological laboratories and why there are so many important professorships of pathology which include nearly every first-class medical school, and so many fairly important positions in pathology unfilled.

Reflections of this sort make us approve of the organization of the American Society of Clinical Pathologists and to wonder if pathologists in teaching positions would not be doing a service in promoting their subject if they, too, would combine in insisting upon the financial value of their special knowledge when applied to practice.

The increased dignity that comes with earning capacity alone would be an inducement for men to enter the field of pathology, while the possibility of earning a living in the advent of failure in academic advancement would make the decision towards pathology less venture-some.

These reflections, while based upon an analysis of the situation in pathology, lead us to no definite remedial conclusion. In France in one important medical center a movement has begun with the object of elevating the pathologist to a consultant's status in medical practice. Here in Boston for many years, it is well to remember, that at the Harvard Medical School the custom of the Department of Pathology does not permit individuals to receive fees for diagnoses. Bills are rendered by the department and all fees collected go into a fund used for defraying expenses of research and for the maintenance of a free autopsy service for the benefit of the physicians in the vicinity of Boston.

The tradition of the pathologist that it is his duty to encourage the use of scientific methods in medicine is hard to down; does it receive the encouragement it deserves?

MEETING OF THE SOUTHERN MEDICAL ASSOCIATION.

THE programme for the meetings of this body in Chattanooga covering November 13, 14, 15 and 16, gives evidence of careful planning, for eighteen sections covering as many departments of medicine, surgery, hospitals, public health and medical education, have schedules of exercises.

Liberal provision has been made for the entertainment of ladies and other guests. The programme occupies eleven pages of the *Journal of the Southern Medical Association*, and with the exception of the programme of the meetings of the A. M. A. is more voluminous than any medical programme within the memory of the writer.

This is the sixteenth annual meeting of this Association, which has a membership of about seven thousand. The success of these meetings illustrates the advantages of bringing States into closer relations for the interchange of opinions and consideration of problems of common interest.

Our New England States could advantageously unite in meetings patterned after those arranged by the Southern Medical Association.

News Notes.

BOSTON CITY HOSPITAL.—A staff clinical meeting was held in the Cheever Surgical Amphitheatre Friday, November 17, at 8 P.M. The following subjects were discussed: Presentation of current explanations of the mechanism involved in the production of Tremor; interpretation, and significance; Henry Viets. Mechanism of production and functional interpretation of Convulsions; Harry C. Solomon. Physiological mechanism and theories explaining the paresthesias (numbness, burning, tingling sensations); Abraham Myerson.

SPRINGFIELD ACADEMY OF MEDICINE.—The November meeting of the Springfield Academy of Medicine was held at 137½ State Street, Tuesday, November 14, 1922, at 8:30 P.M. Dr. J. P. Hogue of New York City read the paper of the evening, entitled "Hernia." Dr. Hogue is Associate Professor of Surgery at Cornell Medical School, New York; attending surgeon at the French Hospital, New York City; and attending surgeon at the Ruptured and Cripple Hospital, New York City.

A MISSTATEMENT WAS MADE in the editorial headed "The College of Surgeons—Boston," which appeared in the JOURNAL Nov. 2nd, 1922. Dr. Henry J. Bigelow was mentioned as the man who created Mt. Auburn Cemetery. This is not correct. Dr. Jacob Bigelow, his father, founded Mt. Auburn, "and also drew the plans for the three principal architectural structures there—the Gate, the Tower and the Chapel, which latter is now the Crematory." The writer regrets the mistake. The general fact, however, of the relationship of well-known Boston surgeons to matters of importance in Massachusetts, not always entirely medical, remains not only true, but confirmed and even extended by this correction, to architectural adornments of Mt. Auburn, as well as to its foundations of earth and granite.

[J. B. B.]

DEATH RATE IN BOSTON.—During the week ending Nov. 11, 1922, the number of deaths reported was 221, against 182 last year, with a rate of 15.09. There were 32 deaths under one year of age, against 24 last year. The number of cases of principal reportable diseases were: Diphtheria, 64; Scarlet Fever, 36; Measles, 56; Whooping Cough, 60; Typhoid Fever, 2; Tuberculosis, 31. Included in the above, were the following cases of non-residents: Diphtheria, 7; Scarlet Fever, 7; Whooping Cough, 1; Tuberculosis 8. Total deaths from these diseases were: Diphtheria, 1; Scarlet Fever, 1; Whooping Cough, 1; Tuberculosis 11. Included in the above, were the fol-

lowing cases of non-residents: Scarlet Fever, 1; Tuberculosis, 1.

THE WORCESTER DISTRICT MEDICAL SOCIETY.

The annual open meeting of the Worcester District Medical Society was held in Horticultural Hall, Worcester, Nov. 8, 1922, at 8:15 P.M. The meeting was called to order by President Dr. George E. Emery, who in turn turned it over to Dr. Kendall Emerson, the chairman of the Worcester Committee for the control of cancer, to preside. In introducing the speakers Dr. Emerson said that during the last few years the practice of medicine had enjoyed a revolutionary change, and that today the medical profession is seeking the confidence of the public. The real purpose of the doctors of today is the prevention of disease, and they have interested the public in many of the great problems of the prevention of disease, such as the anti-tuberculosis campaign, and now they are seeking to interest the public in the control of cancer.

Dr. Ernest L. Hunt was then introduced and gave a short talk on the cancer problem as it concerned Worcester. He said that cancer was a disease of middle life and carried off the adult at a time of life when he should be at the height of his efficiency.

Worcester lost by death from cancer during the year of 1921, 212 people. During this year the Worcester City Hospital has admitted to its wards 128 cases of cancer, of which number 70 were too far advanced to give any hope from treatment. Worcester is well equipped to cope with the situation if the patients will consult physicians early enough.

Dr. Frederick L. Hoffman (LL.D.), Director of the American Society for the Control of Cancer, and Consulting Statistician for the Prudential Life Insurance Company of America, gave the principal address of the evening. He said that during the time that he had been interested in the control of cancer he had seen the mortality from the disease rise steadily from 75,000 yearly in the U. S. to 90,000, and soon it would be 100,000 per year. Cancer is the only disease whose mortality is still growing. This is the story the world over. However, the liability to cancer is increasing faster than the death rate, and if it were possible to ascertain the number of cancer cases throughout the country and the number of successful operations and the number of lives saved, the evidence would most conclusively support the conviction that cancer control was being realized. Cancer is most common among the well to do and frequently among those who have never been sick a day in their lives. It is very rare among the Indians and among the

Chinese. The cause of cancer seems to lie in our modern way of living. Excess in weight is a more serious body abnormality than underweight. The disease is not contagious. No nurse has ever been known to contract the disease from her patient. Cancer can not be prevented, but death from cancer can be prevented.

After the lecture by Dr. Hoffman the two-reel film of the State Board of Health was shown, entitled "The Reward of Courage."

About 400 people attended the meeting, and the morning *Telegram* gave a column on the front page to the publicity end.

The Staff of the Worcester City Hospital has voted to form, at the request of the Surgeon General, a Reserve Hospital Unit, and have elected Dr. Frank George as commanding officer. The personnel of the Unit will be made up of members of the Staff of the Hospital and other physicians from the county.

THE HARVARD MEDICAL SOCIETY.

The first meeting of the Harvard Medical Society for 1922-1923 was held Tuesday evening, November 7, at the Peter Bent Brigham Hospital, Dr. Cushing presiding.

Dr. H. F. Newton presented a case of echinococcus cyst of the liver which had been operated upon by Dr. David Cheever. The striking feature of the case was that the enlarged cystic liver found at operation was considered by the staff, previous to operation, an enlarged spleen.

Dr. F. C. Shattuck remarked in discussion that an enlarged left lobe of the liver may be readily mistaken for an enlarged spleen, and that the diagnosis of echinococcus disease is often difficult.

Dr. S. B. Wolbach outlined the pathology of echinococcus disease and demonstrated the microscopic appearances of the characteristic daughter cysts with their hooklets.

Dr. John Donley of Providence gave a paper illustrating the reactionary point of view of John Riolan in regard to Harvey's discovery of the circulation and showed that even in the year 1650 it was impossible for a conservative clinician to check the progress of medical science in the hands of men with an experimental viewpoint.

In discussing this paper Dr. F. C. Shattuck wondered what the generation three hundred years from now would think of ourselves and wondered how many of us will be considered the Riolans of our own time and how many the Harveys.

Dr. Henry Richardson of New York reported his studies on metabolism which he has been recently conducting at the Russell Sage Institute. He demonstrated clearly how different the food actually oxidized is from that ingested

and offered the hope that in future more stress would be laid upon the food burned than upon the food eaten in the treatment of those cases of metabolism in which dietotherapy is of the greatest importance.

Dr. Richardson's paper was discussed by Dr. E. P. Joslin, who was appreciative of the significance of Dr. Richardson's experiments and the way in which they had been planned.

HARVARD MEDICAL SCHOOL APPOINTMENTS.

At a meeting of the President and Fellows of Harvard College in Boston, October 30, 1922, it was voted to make the following appointments for one year from September 1, 1922:

James Percy Baumberger, Teaching Fellow in Physiology; *Thomas Jefferson Duffield*, Instructor in Vital Statistics.

Anatomy—*Harold Valmore Hyde*, Assistant; *Carl Edward Johnson*, Assistant.

Bacteriology—*Walter Wendell Fray*, Austin Teaching Fellow; *Francis Browne Grinnell*, Assistant; *Harry Weiss*, Assistant.

Biological Chemistry—*M. R. Everett*, Teaching Fellow.

Medicine—*William Bradley Breed*, Assistant; *Henry Jackson, Jr.*, Assistant.

Orthopedic Surgery—*Robert Bayley Osgood*, Professor.

Pathology—*Trevor Goff Browne*, Assistant; *Robert Joseph Kirkwood*, Assistant; *Monroe Jacob Schlesinger*, Assistant; *Michael Joseph Conroy*, Instructor.

Pediatrics—*Edwin Theodore Wyman*, Instructor; *Bronson Crothers*, Assistant; *Robert Dudley Curtis*, Assistant; *Robert Ogden Dubois*, Assistant; *Paul Waldo Emerson*, Assistant; *Martin Joseph English*, Assistant; *Hyman Green*, Assistant; *Francis Browne Grinnell*, Assistant; *Arthur Bates Lyon*, Assistant; *Arthur Roland Newsom*, Assistant.

Preventive Medicine and Epidemiology—*Harold Everett Smiley*, *Charles Follen Folsom* Teaching Fellow.

Surgery—*William Justus Merle Scott*, *Arthur Tracy Cabot* Fellow.

INSTRUCTIVE DISTRICT NURSING ASSOCIATION.

BABY HYGIENE ASSOCIATION.

A marked increase in the prevalence of the respiratory diseases has made October the heaviest month since May—2,567 new patients were admitted—an increase of 10%, over those of the same period last year and 25,765 visits made. By the prevalence of these diseases October shows the same peculiarity that marked the entire summer and fall.

There were 81 new cases of pneumonia; 112 of bronchitis; 16 of grip and 67 of other respiratory diseases, making more than twice as many as at this time a year ago.

Typhoid fever dropped to only 1 new case. All the other communicable diseases showed an increase: 45 new cases of measles; 34 of whooping cough; 11 of chicken pox and mumps; 2 new cases of infantile paralysis of recent onset.

In contrast to the increase in the other diseases was a striking drop in cancer and diseases of the heart.

The service at the time of delivery reached the highest figure in its history.

During the month of October 576 new babies came to the Baby Hygiene conference, and of these 336 were under three months of age. The total conference attendance for the month was 5,457.

As the winter with its stormy days comes on, the conference attendance will necessarily be less, but the visits in the homes for individual instruction to the mothers of 9,464 babies goes on continuously at the rate of about 10,400 per month.

Miscellany.

THE SUPPRESSION OF NEEDLESS NOISE.

The Commissioner of Health of Chicago has entered upon a campaign to eliminate unnecessary noise in Chicago, under authority conferred in Section 1425 of the Sanitary Code, which reads as follows:

"(Matters and Things Detrimental to Health)—No building, vehicle, structure, receptacle or thing used or to be used for any purpose whatever shall be made, used, kept, maintained or operated in the city, if the use, keeping, maintaining or operating of such building, vehicle, structure, receptacle or thing shall be the occasion of any nuisance, or detrimental to health."

It is claimed that careless truck and automobile drivers are the worst offenders.

PERTUSSIS VACCINE.

The Department of Health, City of New York, has appointed a committee to consider the value of whooping-cough vaccine. The committee has decided that a definite announcement of the preventive value of the vaccine should be deferred until results of the study which has been inaugurated by the Bureau of Laboratories shall have been tabulated. A preliminary statement relating to the therapeutic value of the vaccine has been published in the Bulletin for Nov. 11 and is as follows:

"As to the therapeutic value of pertussis

vaccine, it is the judgment of the Committee that it seems to be a symptomatic remedy which has appeared to have some value in abating the severity and frequency of the paroxysms. Whether the good results attributed to whooping-cough vaccine are due to a non-specific protein reaction is a question which cannot be answered at this time. In all events, the favorable judgment of the value of whooping-cough vaccine in symptomatic treatment of whooping-cough, which has been recorded by a number of clinicians of good standing, warrants us to encourage the continued trial of whooping-cough vaccine in the treatment of pertussis, especially since the treatment is harmless.

"The Committee is unanimous in its recommendations that whooping-cough, in view of its serious complications and sequelae, and its high mortality rate, should be regarded as a major communicable disease, and that parents and physicians should be instructed and urged to recognize that strict quarantine is as essential in this disease as in the other major communicable diseases. Whenever the maintenance of strict quarantine is not possible, a patient suffering from this disease should be sent at once to one of the hospitals of the Department of Health, so as to remove a source of infection that may be responsible for the spread of the disease.

"J. J. BLUMENTHAL, M.D., Act. Director, Bureau of Child Hygiene.

"ROBERT J. WILSON, M.D., Director, Bureau of Hospitals.

"L. H. HARRIS, M.D., Director, Bureau of Preventable Diseases.

"WM. H. PARK, M.D., Director, Bureau of Laboratories.

Committee."

AMERICAN RELIEF ADMINISTRATION.

Moscow.—Dr. John E. Toole, Branford, Conn., district physician of the American Relief Administration at Saratov, pays a high tribute to the Russian doctors of that region, who until the arrival of American medical supplies waged a hopeless war against disease under almost unbelievably hard conditions.

"Medical personnel," says Dr. Toole in his latest report, "is usually intelligent and enthusiastic. They have borne up under unimaginable difficulties. Without anaesthetics, ligature material and clean dressing material, they have performed major operations with excellent results considering the difficulties. They have been without the most essential drugs many times and have reverted to various herbs of recognized therapeutic value. They have been at times half starved themselves, and there are few doctors who have not had the three varieties of typhus. Practically all of the doc-

tor-inspectors whom I sent into malaria districts have contracted malaria. Many physicians died during the typhus epidemic last spring, but they are heroic and must be deemed a saving feature of demoralized Russia. Their number seems adequate and the distribution has been more equalized during the past few months, and districts where there was no doctor last spring are now supplied with one.

"The poverty and inability of patients to pay for physicians' services has made the finances of the Russian doctors especially precarious and the majority of them are living in extreme poverty."

Three medical specialists not far from Moscow city, who wish to carry on the duties of their professions unhampered by the worry of where the next meal is coming from for their families this winter, have petitioned the American Relief Administration to extend them credit for one year for food packages provided them monthly.

Too proud to ask for charity and yet anxious, apparently, to conduct their work without the burden of worry, they have made a business proposition to the A. R. A. in which they offer to pay at the end of the year the cost and expenses of forwarding American food packages. They stipulate that if at the end of the year unforeseen circumstances prevent payment they will ask for an extension of another year in which to make good.

To prove their standing and guarantee the debt, they describe in detail the property they own and the members of their family. One is an authority on pediatrics, another head of an eye disease hospital, and a third a director of a children's home. One has a wife and two daughters and a son. Another has a wife and three small sons, while the third has a wife, son and two daughters.

THE LIABILITY OF PHYSICIANS UNDER THE NEW YORK SANITARY CODE.

The New York City Sanitary Code has the following section:

Section 100. Acts tending to promote spread of disease prohibited.—No person shall by any exposure of any individual sick of any infectious disease, or of the body of such person, or by any negligent act connected therewith, or in respect of the care or custody thereof, or by a needless exposure of himself, cause, contribute to, or promote, the spread of disease from any such person, or from any dead body. S. C. Sec. 143.

Under this provision the Health Department of the City of New York has brought action against a physician because he directed a mother to take her child to the office of the Department

of Health after a diagnosis of diphtheria had been made.

The doctor sent the following note with the mother:

"Baby S. has a positive culture, surely laryngeal. Mother of baby does not believe. Kindly inject."

The *Bulletin* publishes the following comment:

In the course of the child's travels through the streets and in public conveyances, to the Department, and within the office building of the latter as well, a number of children were obviously imperiled by contact with this diphtheria patient. It would seem that a physician who has received instruction as to the mode of transmission of communicable diseases, would have seen at once that the action which this mother was counselled to take constituted a grave source of danger to others, and was in conflict with elementary medical teachings. He certainly showed a serious lack of judgment.

DIPHTHERIA AND THE SCHICK TEST IN INDIANA UNIVERSITY.

BLOOMINGTON, IND., October.—Modern medical science works wonders. The recently discovered Schick test is largely responsible for the stamping out within 19 days of a serious epidemic of diphtheria among 2900 students attending Indiana University. The test consisted of a hypodermic injection in the arm of a minute quantity of diphtheria toxin, which determined by the resulting color of the skin the immunity or susceptibility to diphtheria of the subject. More than 1100 tests were given and the majority of the 490 students showing susceptibility took the preventative antitoxin. Vigorous quarantine of students exposed to the disease until they could be examined, together with prompt isolation of cases for treatment in the university's private hospital, contributed to the early wiping out of the epidemic. Among the 85 cases not a single serious illness developed. No ill effects resulted from the use of the antitoxin.

U. S. DEPARTMENT OF LABOR. CHILDREN'S BUREAU.

A comprehensive directory of 861 local child health agencies in the United States has just been issued by the U. S. Department of Labor through the Children's Bureau. These agencies are actively engaged in the promotion of child health through maternity care, infant care, and the care of the child of preschool age. They serve States, counties, and urban areas of 10,000

or more inhabitants. The material was obtained by means of a questionnaire which called for the name of the organization, the address, the name of the executive, the number of paid and volunteer workers, and the scope of the work.

For convenience in consultation, the directory includes a list of agencies arranged by State and city; an alphabetical list by States, of agencies serving State-wide, county, and urban areas; and a classification of agencies according to whether they provide maternity care, infant care, and the care of children of preschool age.

"THINK I'M STRONG ENOUGH TO WORK, DOCTOR!"

Forty-three thousand boys and girls ask this question each year. The law *requires* every child between 14 and 16 years of age who goes to work to have a thorough physical examination. Yet how often a child physically unfit for work, is admitted to industry! The Massachusetts Department of Public Health, with the assistance of the Massachusetts Child Labor Committee, published an answer to the youngster's question. The pamphlet, "That Depends," is a plea for more careful consideration of children going into industry—a plea for health certification backed by thorough medical examination. As the familiar saying goes "an ounce of prevention is worth a pound of cure," the pamphlet suggests a short cut to prevention—or at least a straight road. It is distributed free by the Health Department to anyone in this State.

SMALLPOX IN NEW YORK STATE.

There have been about one hundred and fifty cases of smallpox in New York State outside of the City of New York this year.

Two recent outbreaks, one in the western part of the State and the other on the St. Regis Reservation, have caused anxiety on the part of the Public Health Department.

Efforts are being made to induce the people to seek protection through vaccination. Physicians and local health officers have been appealed to to cooperate.

CONNECTICUT HEALTH STATE COMMISSIONER.

The Hartford *Times* announces the retirement of Dr. John T. Black, State Health Commissioner, who will associate himself with the Aetna Life Insurance Company.

The Governor has appointed Dr. Stanley H. Osborn as Commissioner of Health. Dr. Osborn has been epidemiologist in the Connecticut

Bureau of Preventable Diseases since 1920. He is a graduate of Tufts Medical College and the Harvard Graduate School of Medicine. He served overseas during the War.

Dr. Black was appointed Health Commissioner July 1, 1917. He has endorsed Dr. Osborn for the position made vacant by his resignation. Under Dr. Black the health conditions in Connecticut have steadily improved.

RÉSUMÉ OF COMMUNICABLE DISEASES.

OCTOBER, 1922.

GENERAL PREVALENCE.

Diseases showing a marked increase over the previous month are as follows: chicken pox, diphtheria, measles, mumps, lobar pneumonia, scarlet fever.

The more prevalent diseases were reported as follows:

	October 1922	September 1922	October 1921
Chicken pox.....	199	53	248
Diphtheria.....	1026	578	887
Measles.....	686	269	312
Mumps.....	190	67	139
Pneumonia, lobar..	237	86	191
Scarlet fever.....	554	281	431
Whooping cough...	634	637	156
Gonorrhea.....	480	493	434
Syphilis.....	137	179	170

RARE DISEASES.

Anterior poliomyelitis was reported from Barnstable, 1; Boston, 6; Braintree, 1; Brookline, 1; Chilmark, 1; Dennis, 3; Everett, 1; Fairhaven, 1; Falmouth, 1; Grafton, 1; Lynn, 1; Malden, 1; New Bedford, 1; Randolph, 1; Rockport, 2; Saugus, 1; Wakefield, 1; Webster, 1; Weymouth, 1; Winchendon, 1; Worcester, 1; total, 29. (There were 63 cases reported last month and 27 for the corresponding month last year.)

Dog-bite requiring anti-rabic treatment was reported from Beverly, 1; Boston, 3; Great Barrington, 3; Lowell, 3; Medford, 3; Stockbridge, 3; Tewksbury (State Infirmary), 1; Winthrop, 1; total 18.

Dysentery was reported from Boston, 1.

Encephalitis lethargica was reported from Gloucester, 1; Lawrence 1; Longmeadow, 1; Lynn, 2; Newburyport, 1; Newton, 1; Waltham, 1; total, 8.

Epidemic cerebrospinal meningitis was reported from Fall River, 2; Lawrence, 1; Mansfield, 1; Newton, 1; Somerville, 1; Worcester, 1; total, 7.

Hookworm was reported from Boston, 2.

Malaria was reported from Boston, 3; New Bedford, 1; Pittsfield, 1; Uxbridge, 1, total, 6.

Pellagra was reported from Boston, 1; Fall River, 1; Wellesley, 1; total, 3.

Septic sore throat was reported from Andover, 1; Boston, 2; Harwich, 7; New Bedford, 2; total, 12.

Tetanus was reported from Boston, 4; Dartmouth, 1; Lowell, 1; Milford, 1; total, 7.

Trachoma was reported from Belmont, 1; Boston, 1; Lawrence, 1; Newton, 1; Medway, 1; Woburn, 1; total, 6.

Trichinosis was reported from Boston, 3; Brookline, 1; total, 4.

IMPORTANT ANNOUNCEMENT.

The medical profession will be interested in the announcement that the Abbott Laboratories of Chicago have purchased the Dermatological Research Laboratories of Philadelphia. This is an advance step for the Abbott Laboratories, and will give them deserved recognition among the leading manufacturers of medicinal products.

It will be remembered that the Dermatological Research Laboratories were the first in the United States to produce Arsphenamine during the war, where there was such a scarcity of this article; and these Laboratories became well known to the medical profession for their patriotic attitude in developing and manufacturing medicinal preparations in this country. By this purchase of the "DRI" products, the Abbott Laboratories inherited their prestige.

The Abbott Laboratories acquired control of the Dermatological Research Laboratories on November 1st, and are continuing to operate them in Philadelphia under the direction of Dr. Geo. W. Raiziss, head of the Department of Chemistry, and his corps of specially trained assistants. Orders for "DRI" products will be promptly filled from the Philadelphia Laboratories or from their branches or distributors.

THE NEW HOME OF HYNSON, WESTCOTT & DUNNING OF BALTIMORE.

This national drug firm has just erected and occupied its own building at Charles and Chase Streets, Baltimore. The building is artistic in appearance and adapted to accommodate the several departments of their rapidly developing business, which began in a small way in 1889, but has now grown to a million a year, with an organization of 125 people. Their unique sales department alone comprises 19 men, who visit physicians in all parts of the United States, but do not sell goods. Thirty-five of their products have been accepted by the Council. None of

their preparations are offered direct to the public, but are introduced to the medical profession for the use of physicians and their patients. Mr. H. P. Hynson, one of the founders, died in 1921, but their growing business has now been established in new quarters under the immediate supervision of Messrs. James W. Westcott and H. A. B. Dunning (the latter being the active administrator), with a highly trained force, equipped to meet promptly the demands of the medical profession anywhere and at all times.

Obituaries.

WALTER BREWSTER PLATT, M.D.

Walter B. Platt, hospital superintendent and pediatricist, was born at Waterbury, Connecticut, Dec. 20, 1853, and died of heart disease at his home in Baltimore Oct. 30, 1922. He was the son of Gideon Lucien and Caroline (Tudor) Platt. His father, a physician and surgeon, and president of the Connecticut State Medical Society, was a man of great energy, rectitude, self-control and kindness. Richard Platt, the founder of the Platt family, came from Hertfordshire, England, in 1638, and settled in Milford, Connecticut. Other ancestors of note were: Thomas Buckingham, who emigrated from England in 1638, to New Haven, Connecticut; Owen Tudor, who went to Massachusetts from Wales between 1620 and 1636; Deacon William Gaylord, who emigrated from England in 1630; Joseph Loomis, who came from England in 1638; Elder William Brewster (pastor of the Pilgrims on the *Mayflower*), in 1620; Doctor Elihu Tudor, surgeon (1733-1826), who was with General Wolfe of the British army at the capture of Quebec and Havana.

When Platt was a boy, he lived in a small town, where, he said, "among other duties I was made to take entire care of a horse for a time," a discipline which he thought most valuable. He early showed a love for chemistry, zoölogy and botany, and in reading found most helpful works in natural science, such as those of Huxley, Herbert Spencer, and Sir John Lubbock. Platt received his early education in the public schools and at Williston Seminary, Easthampton, Massachusetts. He then entered Yale University, and received the degree of Ph.D. in 1874. From that date until 1879 he studied at the Harvard Medical School, graduating with the degree of M.D. in the latter year. Then he pursued post-graduate courses in medicine at the Universities of Berlin, Vienna and Heidelberg and obtained membership in the Royal College of Surgeons of England, being made a fellow of that college, by examination, in 1883.

In the year 1872 Dr. Platt was collector of

specimens of natural history in the Yellowstone expedition of the United States Geological Survey. In 1878 he was both house surgeon and assistant to the superintendent at the Boston City Hospital. From 1884 to 1889 he was surgeon to the Bay View Asylum, Baltimore, and during the same years was demonstrator of surgery at the University of Maryland. First appointed in 1886, he was superintendent and surgeon of the Robert Garrett Hospital for Children. In 1884 he published a translation with notes, of Ultzman's "Pyuria." Among his memberships were the Delta Psi Fraternity, the University Club, the Reform League, the Civil Service Reform Club, the American Economic Association, the American Association for the Advancement of Science, the National Economic League. Of the numerous professional societies were the American Medical Association and the Medical and Chirurgical Faculty of Maryland. For many years he was a member of the council and honorary surgeon to the Society of Colonial Wars. In politics Dr. Platt was identified with the Republican party, though he twice voted for Cleveland. He was a vestryman in St. John's Episcopal Church, Kingsville, an office he held from 1903. For exercise and recreation he turned to camping, riding, rowing and traveling by sea to tropical countries. He said "I am a strong believer in moderate indulgence in athletic exercises, but opposed to violent competitive games. I think their influence is not physically good on those who take part in them."

On December 4, 1889, Dr. Platt married Mary P. Perine of Baltimore, daughter of the late Glenn Perine and niece of Mrs. H. Irvine Keyser. They had four children: Washington, David, Mary (now Mrs. C. C. Hall), and Lucien, who died from influenza while in the Engineers' Training Camp during the World War.

Dr. Platt was a man of most upright character, greatly respected by a large group of friends and greatly beloved by a long list of devoted patients. To the management of the Robert Garrett Hospital, through the many years of his service, he gave his time and thought without stint, and the great success of the work of this institution has been due in very large measure to his good judgment and continued interest. Once when asked to express his advice to a young man beginning his career he offered this suggestion: "associate early with men of high ideals and successful achievement. Take regular, moderate physical exercise. Get your education at the best schools and universities. Concentrate professional energy. Keep up general culture through life. Resolve to entertain no ideals or beliefs except such as are sound and ultimately useful to mankind."

[H. B. J.]

GEORGE PRENTISS MORGAN.

Word has been received of the death, November 8, 1922, at Dover, New Hampshire, of Dr. George P. Morgan of that city, at the age of 61.

He was born at New Gloucester, Maine, June 22, 1861, graduated in the medical class of 1888 at Bowdoin College, and settled in Dover the following year. In 1892 he joined the New Hampshire Medical Society, and he also had membership in the Maine Medical Association and the American Medical Association. Much of his practice was in the domain of surgery, he being surgeon-in-chief to the Wentworth Hospital.

Correspondence.

IN RE ZONITE AD., CANCER WEEK AND N. H. CHIROPRACTIC.

November 9, 1922.

Mr. Editor:

(1) A fine editorial, but unless active measures are taken, only pop-gun work; chiropractic ditto.

(2) Two powerful causes for the mortality—Christian (?) Science (?) and Lydia Pinkham—the former used by fanatics; the latter by the ignorant and gullible — backed by the Boston Herald and a thousand other particeps criminorum. Three deaths (two of brides) from latter, and one from former cause (turn these numbers right around, please) recently in my own work—one, a refined and rich woman who presented a case so horrible its details would make you shudder; ten hours after being called out of town "only to make a diagnosis," death ensued.

This morning's mail brings me a letter from Dr. W. A. Evans (*Chicago Tribune-Boston Herald*) corroborating my own experiences!

Fraternaly,
James Brown Thornton.

THE SCHICK TEST IN NEWTON.

November 8, 1922.

Mr. Editor:

Eighteen months have elapsed since the Newton Board of Health offered the Schick test and T. A. immunization of susceptibles to the children in the public schools and such others as might desire it, and it may not be out of place to publish our results.

During April, May and June, 1921, 1000 persons were tested and subsequently 200 more were done, making a total of 1200 persons, all but 50 being under 16 years of age, on our lists.

Of this number 258 were found to be naturally immune and 50 others were immunized and later shown, by test, to have acquired immunity, so that we have on our lists 308 persons who are immune and 892 known to be susceptible, but who have neglected or refused to be immunized.

These two groups have been under observation for a period of 16 months and during that time each case of diphtheria, as reported, has been checked against our lists with the result that none of the 308 immunes have developed diphtheria, while of the 892 susceptible, 10 have been reported as having diphtheria, not only bacteriologically but clinical.

Our number of immunes is as yet too small to have had any effect in reducing the number of cases of diphtheria reported, but we believe that we have shown that persons showing a negative Schick, whether due to natural or artificial immunity, are protected from diphtheria and we intend to continue our work in the hope of being able to show at some future period, that we have increased our immune population and so reduced our cases of diphtheria.

FRANCIS GEO. CURTIS, M.D.
Chairman, Newton Board of Health.

THE FIRST MEDICAL COLLEGE HOSPITAL IN THE UNITED STATES.

Mr. Editor:

In your issue for October 26th, 1922, page 600, I notice that Dr. Thomas S. Brown mentions the fact that in 1893 the University of Pennsylvania and the Johns Hopkins Hospital had their own hospitals, which were utilized for the education of medical students. The inference was that no other medical school had its own hospital.

Evidently, the writer is not aware of the fact that the Jefferson College Hospital was opened on September 17th, 1877—sixteen years earlier than the date which is given above. Moreover, as long ago as 1860, when I entered the Jefferson as a student, we had a small hospital of ten or twelve beds in two rooms, one for men and one for women and children.

The writer raises also the question of any harm arising to patients from ward classes.

I venture to make the following extracts from my address as President of the Sixth Congress of American Physicians and Surgeons, held in Washington on May 12th, 1903:—

"I have lived through the period of the establishment of hospitals in many of the smaller cities and towns, and in some cases even villages in this country, for it was a rare thing in my early professional life for any except the larger cities to have hospitals. The moment that a hospital is established with its medical and surgical staff, that moment a new era has dawned on the community in which the hospital is established. More careful methods are introduced, greater cleanliness is observed, hygienic conditions are bettered, laboratory methods are inevitably introduced in time. . . . It is sometimes objected by those who are not familiar with the actual facts that this method of actual bedside instruction does harm to the sick. I speak after an experience of nearly forty years as a surgeon to a half dozen hospitals and can confidently say that I have never known a single patient injured or his chances of recovery lessened by such teaching. . . .

Who will be the least slovenly and careless in his duties: he who prescribes in the solitude of the sick chamber, and operates with two or three assistants only, or he whose every movement is eagerly watched by hundreds of eyes, alert to detect every false step, the omission of an important clinical or laboratory investigation, the neglect of the careful examination of the back as well as the front of the chest, the failure to detect any important physical sign or symptom? Who will be most certain to keep up with the progress of medical science: he who works alone with no one to discover his ignorance, or he who is surrounded by a lot of bright young fellows who have read the last *Lancet* or the newest *Annals of Surgery* and can trip him up if he is

not abreast of the times? I always feel at the Jefferson as if I were on the run with a pack of lively dogs at my heels. I cannot afford to have the youngsters familiar with operations, means of investigation, or newer methods of treatment of which I am ignorant. I must perforce study, read, catalogue, and remember, or give place to others who will. Students are the best whip and spur I know."

Yours very truly,

W. W. KEEN.

DISEASES REPORTED TO MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH.

WEEK ENDING NOVEMBER 11, 1922.

Disease.	No. of Cases.	Disease.	No. of Cases.

BOSTON ASSOCIATION OF CARDIAC CLINICS.

SCHEDULE OF MEETINGS.

The first meeting was held Nov. 16 at the Massachusetts General Hospital. The subject discussed was "Syphilis of Heart and Aorta," by Dr. Walter P. Anderson, Presbyterian Hospital, New York City. Dr. William D. Reid, Boston Dispensary and Boston City Hospital. Discussion opened by Dr. William D. Smith, Massachusetts General Hospital.

Succeeding meetings will be held Thursday, January 18, 1923, at 8:15 p.m. Boston Lying-In Hospital (now Hospital). Pregnancy and Heart Disease.

Drs. William B. Breed and Paul D. White, Massachusetts General Hospital. Dr. Burton E. Hamilton, Boston City Hospital and Boston Lying-In Hospital.

Thursday, March 15, 1923, at 8:15 p.m. Boston City Hospital. Prevention and Relief of Heart Failure.

Rheumatism and Chorea and Heart Disease. Congenital Heart Disease. Thursday, May 17, 1923, at 8:15 p.m. Children's Hospital.

PACIFIC NORTHWEST MEDICAL ASSOCIATION.

The September issue of Northwest Medicine contains the minutes of the first scientific session of the Pacific Northwest Medical Association, held in Spokane, Washington, July 6 to 8, 1922. Among the papers read and published in this issue are three by Dr. Henry A. Christian of Boston: "Certain Phases of the Chronic Nephritis Problem," "Hemolytic Jaundice, Pernicious Anemia, Akaptonuria, and Orthostatic Albuminuria," and "Digitalis and Quinidine in the Treatment of Certain Types of Chronic Cardiac Disease."

Dr. W. B. Cannon, of Boston, spoke on "New Evidence Regarding the Nervous Control of the Thyroid Gland."

PUBLIC HEALTH LECTURERS FOR THE YEAR 1922.

The Committee on Public Health of the Massachusetts Medical Society has been able during the past three years to arrange with well known specialists in various medical fields to give talks at meetings of the District Medical Societies on subjects of interest and importance to all practitioners. It is a pleasure to announce that a similar arrangement has been made this year and that the gentlemen named below are willing, without expense to the District Society, to give occasional talks of thirty to forty minutes on subjects relating to the promotion of public health, extending opportunity for questions and discussion. It is suggested that medical societies consider meeting at neighboring public institutions, since such meetings have been most successful in the past, particularly at the tuberculosis sanatoria and state hospitals for the insane.

José Penteado Bill, M.D., Doctor of Public Health.
Specialty: Preventive Medicine.

Frank C. Dunbar, M.D., Bacteriologist, Instructor in Bacteriology and Pathology, Tufts College Medical School. "Methods of Technique in Collecting Specimens."

Walter E. Fernald, M.D., Superintendent, Massachusetts School for the Feeble-minded.

Timothy Leary, M.D., Professor of Pathology, Tufts College Medical School; Medical Examiner, Suffolk County.

Edwin H. Place, M.D., Physician-in-Chief, South Department, Boston City Hospital. Specialty: Contagious Diseases.

C. Morton Smith, M.D., Chief of Department of Syphilis, Massachusetts General Hospital.

George Gilbert Smith, M.D., Assistant in Department of Genito-Urinary Diseases, Massachusetts General Hospital. Specialty: Genito-Urinary Diseases.

Lesley H. Spooner, M.D., on Staff of Out-Patient Department, Massachusetts General Hospital. Specialty: Specific Diagnosis and Treatment of Pneumonia.

William C. Woodward, M.D., Ex-Health Commissioner, City of Boston.

George H. Wright, D.M.D., Lecturer on Dental Hygiene, Harvard Dental School. Specialty: Dental Surgery.

Thomas F. Kenney, M.D., Director of School Hygiene, City of Worcester. Specialty: Full time School Health Officer.

Secretaries of District Medical Societies writing to ask for these lecturers will kindly designate the topic, the place and the hour of meeting as well as the name of the desired speaker, thus eliminating

unnecessary correspondence. Please address communications to the Secretary of the Committee, Annie Lee Hamilton, M.D., 164 Longwood Ave., Boston 17.

[Note: The Committee on Public Health feels that this notice may have escaped attention, for few applications have been received. Each lecturer is an authority and would present his subject in an interesting and instructive manner.]

SOCIETY MEETINGS.

DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue.

Barnstable District:—Hyannis, February 2, 1923. (Annual Meeting)—May 4, 1923.

Bristol South District:—Fall River, May 3, 1923.

Essex North District:—Haverhill, (Semi-Annual Meeting)—Jan. 3, 1923. Y. M. C. A. Building, Lawrence, (Annual Meeting)—May 4, 1923.

Essex South District Medical Society meets Wednesday, December 13th, at Beverly Hospital, Beverly, 6 p.m. Speakers: Dr. W. P. Bowers, Managing Editor *Boston Medical and Surgical Journal*; Dr. John D. Adams, Boston; Dr. F. P. Johnson, Beverly. R. E. Stone, Secretary.

Suffolk District:—December 27, 1922; January 31, 1923; February 28, 1923; March 28, 1923; Annual Meeting, April 25, 1923.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexis Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, Hist. The date for each speaker has not been assigned.

Middlesex North District:—Meetings: Wednesday, January 31, 1923.

Middlesex East District:—Jan. 24, 1923. The Nursing Problem. Speaker to be announced later.

March 21, 1923. Mental Factors in Childhood. Paper by Dr. William Healy.

April 28, 1923. Interpretation of Laboratory Findings. Papers by Dr. E. G. Crabtree and one to be announced later.

May 9, 1923. Annual Meeting.

All meetings except the annual meeting will be held at the Harvard Club in Boston. A. E. Small, Secretary.

Worcester District meetings in Worcester, Dec. 13, 1922, Jan. 10, Feb. 14, March 14, April 11 and May 9, 1923, the last named date being the annual meeting.

Massachusetts Society of Examining Physicians:—Meeting and dinner at Copley-Plaza Hotel, Monday, November 27, 6:30 p.m. Symposium on "Back Disabilities." "The Diagnosis of Back Disabilities." Dr. J. W. Sever: lantern slides. "Postural Defects." Dr. Lloyd T. Brown: lantern slides. "Backache in Women with Reference to Industrial Conditions." Dr. Stephen Rushmore. "The X-Ray Standpoint." Dr. A. W. George. Discussion opened by Dr. Francis D. Donoghue. Wm. Pearce Cones, M.D., President, Hilbert F. Day, M.D., Secretary.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

December, 1922. New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 3.30 p.m., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary.

December 26-30, 1922. American Association for Advancement of Science meets in Boston.

January, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston, W. H. Allen, Mansfield, Mass., Secretary.

January, 1923.—Boston Association of Cardiac Clinics. Meeting January 18, 1923, at 8.15 p.m. Boston Lying-In Hospital (New Hospital). Subject: Pregnancy and Heart Disease.

February, 1923. New England Dermatological Society Meeting, February 14, 1923, at 3.30 p.m., in the Skin Out-Patient Department, Massachusetts General Hospital, C. Guy Lane, Secretary.

March, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary.

March, 1923.—Boston Association of Cardiac Clinics. Meeting March 15, 1923, at 8.15 p.m. Boston City Hospital. Subject: Prevention and Relief of Heart Failure.

April, 1923. New England Dermatological Society Meeting, April 11, 1923, at 3.30 p.m., in the Surgical Amphitheatre, Boston City Hospital, C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston, W. H. Allen, Mansfield, Mass., Secretary.

May, 1923. Massachusetts Society of Examining Physicians, (Date and place undecided), Hilbert F. Day, Secretary. Meeting May 31, June 1 and 2, 1923, at French Lick Springs Hotel, French Lick, Ind. H. C. Carpenter, Secretary.

May, 1923. Boston Association of Cardiac Clinics. Meeting May 17, 1923, at 8.15 p.m. Children's Hospital. Subject: Rheumatism and Chorea and Heart Disease.

June, 1923. American Medical Association, San Francisco, June 25-29, 1923. Alexander R. Craig, Chicago, Ill., Secretary.

July, 1923. Massachusetts Association of Boards of Health, July 26, Nantasket, W. H. Allen, Mansfield, Mass., Secretary.

INJURIES TO THE CRUCIAL LIGAMENTS AND AVULSION OF THE TIBIAL SPINE.*

BY CHARLES F. PAINTER, M.D., BOSTON.

I should hardly have had the temerity to bring up the subject announced as the title of this paper merely for the sake of recording four hitherto unreported instances of these lesions. were it not a fact that they are now the not infrequent subject of operative interference because the knee-joint is no longer a *terra incognita* to the operating surgeon. I have been reminded as I have been thinking of this matter that the surgical technique making possible any attempt to deal with these lesions, where necessary by operative methods, has had its origin and development within the span of years during which I have been in practice.

From the latter part of 1894 to the early part of 1896, I was a surgical interne at the Massachusetts General Hospital. During the entire sixteen months of my service, I remember only three or four arthrotomies of the knee performed for non-septic or non-toxic conditions; i.e., clean joint surgery. Three of these were for "joint mice" and one for semilunar cartilage disloca-

tion. Surgeons who were getting quite bold and confident of success in practicing aseptic surgery within the abdominal cavity were very much afraid of the knee joint. The pall of a then recent operative catastrophe hung heavily over surgical practice so far as the knee-joint was concerned. One of the country's foremost surgeons had not long before operated upon a prominent steel magnate of Cleveland, who came on to New York to secure the benefit of his skill in removing a torn semilunar. The wound became infected, and in order to save life a thigh amputation was performed. It was some time before this experience was forgotten because of the prominence of the principals. I recall that my visiting surgeon would, during my period of senior internship, take no chances in opening a knee-joint for a "floating cartilage." If it could be felt easily through the skin and was always readily coaxed from its hiding place, he was willing to cut down upon one when he was able to grasp it between his fingers through the skin, but he could not be persuaded to open the joint before isolating the "mouse" in this way.

Another, with his customary resourcefulness, at about this same time, used a sterilized hat pin with which to transfix the "mouse" after it had been located and before opening the capsule of the joint. It was then easy enough to cut down upon the slippery fragment without fear of its beating a hasty retreat during the process of dissection. This attitude was fairly

*Read before the Boston Orthopaedic Club, April 21, 1922.

representative of that of the entire surgical profession of Boston in 1896.

During the next 13 years, the first three of which I presume it is fair to assume that there was not much, if any, knee-joint surgery being done upon the service, I was helping to develop an adult orthopedic clinic. I think that the report I made in 1910, in conjunction with a colleague, of the results of 204 arthrotomies performed on my service, must have been largely confined to the decade from 1900 to 1910. All cases of arthrotomy were included and the mortality was gratifyingly low, for among that number were a few joints seriously infected before entrance to the hospital wards. It would therefore appear that between 1899 and 1910 a very considerable advance had been made in the technique of knee-joint surgery, an advance which had paved the way leading up to the present attitude of operators who hesitate no more than does the abdominal surgeon to explore, sometimes merely for the sake of satisfying curiosity, and not at all, when there appears some definite pathologic or abnormal anatomic problem to be solved.

This particular group of cases is of course concerned only with abnormal anatomic situations, and this fact makes it desirable to consider what the normal anatomy of the structures involved really is.

We are not, I am sure, sufficiently impressed with the extraordinary stability of the knee-joint mechanism and with the way in which that stability is secured. When one considers the numerous functions to be performed, the power that must be transmitted with the leg in all sorts of positions and under all sorts of strains and stresses, during any and all of which the joint motion must not be blocked or interfered with in any way, together with the extremely slender character of many of the structures by which great resistance must be offered and force applied, we are compelled to marvel at the perfection of design and extraordinary effectiveness of the machine. It is the nicety of adjustment of enveloping capsule and interlocking interarticular ligaments to a mathematically accurate adaptation of the curved articulating cartilages of femoral and tibial surfaces which lays the foundation for this remarkable stability in nearly all positions of the lower leg with reference to the thigh. All this would be of no avail were not the fibrous capsule of the joint made up of the terminal expansions of the powerful thigh muscles, whose actions are so co-ordinated in effecting the two motions of which the knee-joint is capable that the capsule is made taut by the synchronous contraction of these various muscles to just the right extent and at just the right time throughout the full range of motion, from complete extension through to full flexion. It is therefore the fibrous capsule with its various muscular reinforcements, the semilunar cartilages, the

crucial ligaments, and perhaps more than all else the accurate curving of the femoral condyles, by virtue of which they are compelled to maintain such relations to the shallow cup represented by the tibial articular cartilage, that, given a normal muscular co-ordination and tone, the relation of tibia to femur is always that of greatest stability no matter what the angulation at the knee may be; all these factors enter into the stabilization of the knee-joint.

There are really only two situations under which this stabilization may be disrupted. In the first place by violence, of such a nature as to crush down all anatomical structures and, second, a momentary lapse in the synchronous protective activity of the supporting musculature. I will not weary you with a narration of the descriptive anatomy of the knee-joint. It is probably familiar to you all, and if not has necessarily often to be reviewed. I shall content myself with this attempt to give the above composite picture of the results of the normal functioning of these opposed anatomic factors.

Before discussing the subject from the standpoint of the reported cases in the literature, I will give a brief account of my own personal experience with the conditions alluded to in the title.

CASE I. The first patient in whom I recognized a crucial ligament rupture was a medico-legal case which I saw eight years ago. The patient was a young man of 30 who dropped six stories in an elevator. The automatic safety device brought the car to a sudden stop after a six-story drop. There was a capacity load in the car, all of whom were thrown toward the top of the car, which many of them struck, and the patient was buried under several men, his legs being flexed and the lower leg firmly wedged, at the same time that his body was bent over laterally. Everything seemed to be torn apart in his knee; he suffered excruciating pain, could not walk, and there was a rapid accumulation of fluid in the joint. He was taken care of by his local doctor after receiving "first aid" at the Haymarket Square Hospital.

When I saw him some three months after the accident he was still unable to walk with any comfort, and the leg was very unstable. He used a crutch in walking. On examination the leg could not be completely extended and there was hypermobility in two directions. The tibia could be pushed forward upon the femoral condyles and there was more abduction than seemed reasonable, even when it was impossible to completely extend. There was no thickening about the head of the tibia or capsular infiltration. The atrophy was not notable and there were no indications of any inflammatory disturbance. A "cage" splint was applied, with which he found the stability of the joint was greatly increased. He was able to give up his crutch, and in the course of about a year he was nearly

normal as to the function of the knee, though he tired easily.

In this case it would seem that the anterior crucial and the internal lateral ligament was torn. The last time I saw him, more than a year after the accident, there was still a little hypermobility, especially in abduction, and at the same time extension was complete.

CASE II. This case was another crucial ligament tear. The patient was an aviator, 39 years of age. He had met with no serious injury until after the armistice, when he fell out of a window on the first floor of the Barracks at Pensacola, striking heavily on his side with his flexed leg beneath him. He was a tall, powerfully built man, weighing around 180 lbs. There was great pain, complete disability and a large effusion in the joint. He was taken care of immediately at the Naval Hospital there and various treatments were tried, all of which failed to give him a usable leg after nearly two years of treatment. He was admitted to the Naval Hospital in Chelsea, where I saw him. He was walking with a cane, having considerable limp, but not much pain unless he used the leg too much. He was entirely disqualified for duty and was seeking retirement.

On examination the leg was capable of full extension and about twenty degrees short of a right angle in flexion. Anterior displacement of the tibia upon the femur was possible with some slight abduction, even with the leg in full extension. The anterior crucial was the ligament damaged and in this case little harm had been done to the lateral ligament. As the Government was unwilling to retire him until everything had been done that seemed reasonable, I decided to try to repair the torn crucial.

The joint was opened through the median-patellar incision and it was plainly apparent that the anterior crucial had been torn across leaving a very short stump high up in the intercondylar notch, while the longer portion was attached to the tibial spine. The ends were frayed out and one was impressed with the fragile character of the ligaments themselves. Even the posterior, which was not torn at all, seemed singularly inadequate to withstand the strain to which it would seem it must be frequently subject. It was with considerable difficulty, on account of the shortness of the portion of the ligament attached within the intercondylar notch, that silk sutures were passed through the ligament at each of its torn ends. It was not possible to accurately approximate these ends so that the suture had to be regarded as a trellis across which the connective tissue might grow. The wound was closed in the usual manner; kangaroo tendon sutures were passed through the patella, a step which is often omitted as the approximation is usually sufficiently good. His convalescence was uneventful. He was not permitted to have any motion tried, even

passively, for six weeks, and then very gently. It was fully four months before he bore weight on the leg without support other than that afforded by a "cage" splint. At that time he had about right angle flexion, full extension and a fairly stable joint. Since his discharge from the Naval Hospital, which has been followed by his retirement from the service, I have not seen him, but he reports himself as having a serviceable leg.

The length of time which elapsed between the injury and the suture of the ligament is the matter of chief significance in this case, together with the fact that the sutures could not be drawn tight enough to pull the ends of the ligament in contact and yet the procedure converted his condition from one of incapacity so far as any use of the leg was concerned to one of comparative usefulness and activity.

CASE III. Mrs. B., a working woman of 45 years, stepped backward off a porch, a distance of about 3 feet, with a basket of wet clothes in her hands, which she was about to hang upon a line. For a few seconds during the maneuver one foot was on the porch and the other on the ground. As the position was not a dignified one long to maintain, she toppled over to one side, down an embankment, with the result that she was picked up and carried into her house in great pain, referred to the right knee and a rapidly developing effusion. She was kept in bed with ice bags and pillow splint for about two weeks, at the end of which time I saw her, and it was then possible to handle the leg in such manner as to come to some conclusion as to what might have happened within the joint. There was considerable effusion; the leg was in a slightly flexed position and could not be fully extended. There was great tenderness over the joint, particularly about the internal aspect, and attempts to secure motion were very painful. It was possible to slide the tibia forward on the femur and to slip it more posteriorly than it was held, though this last was not noted until she was anesthetized for operation. There was no possible abduction of the leg upon the thigh. The joint was opened through the median-patellar incision. A moderate, blood-tinged effusion was found in the joint and the crucials were both torn. The anterior was frayed out, but the ends were not widely separated. The posterior was not torn all the way through; a thin band seemed to establish a bridge between the main portions. These were both sutured as well as I could, somewhat handicapped as I was by lack of needles of a proper curve. It was the first case of the kind I had ever operated and was done as a sort of an emergency while I was away from home and on a vacation, and I felt it was an unpromising one in every way. Though I was sure I had placed the sutures through the structures that I wished to hold together, I could not see how they were

likely to hold or furnish a basis for anything to develop that would hold. I did not see her for a year. She had been four or five months getting her motion back, but when I saw her she was doing her housework and had no antero-posterior instability of the knee, though she was limited in flexion to a right angle and was a trifle short of complete extension. She was a very heavy woman, and I presume the after-treatment was not pushed very hard by the patient herself.

The feeling of dissatisfaction which I had entertained over the operation when it was completed and the fairly satisfactory functional result which was obtained led me to wonder whether injuries of that sort would not take care of themselves pretty well, any way, for I was, and am still, loath to ascribe the present (3 yrs. postoperative) very satisfactory condition to anything I did at the time of operation.

CASE IV. During the month of December, 1920, I was called to see a young woman who had been injured in a coasting accident at Wellesley. Her right leg was resting upon the side rail of a double runner in a flexed position. The toes of that foot came in contact, in the rapid progress of the "runner" down a hill, with some solid object with sufficient force to violently abduct the leg on the thigh and hurl her and the two companions who were behind her off the "runner" and roll them some distance over the snow. She could not pick herself up and was carried to the College Infirmary, where I saw her the morning after the accident. There was great pain in the knee, with moderate effusion. The leg was flexed to about 30 degrees and was so sensitive that it was impossible to make a satisfactory examination. A radiogram showed that there was a line of fracture at the base of the spine of the tibia and that the whole process was lifted somewhat away from its base. This condition was evident in both views. An ether examination was then given her and no lateral or antero-posterior hypermobility was present, but the leg could not be readily extended. However, with the exercise of gentle pressure in extension full motion in the direction was secured and the leg was put in a cast. Subsequent x-ray examination showed the avulsed tubercle in a better position than at the time of the first observation. The cast was continued for about 5 weeks and then passive manipulation and attempts to regain motion were commenced. She is now in possession of full use of the leg and makes no complaint about it except that when very long on it she finds she tires more easily in that than she does in the other leg. This was a case of uncomplicated fracture or avulsion of the spine of the tibia without any injury to the crucials or the lateral ligaments. It indicates clearly enough that certainly, in those cases where there are no condylar fractures, merely an avulsion of the spine from its base, no open operation is

necessary. Pegging this down with some sort of a bone peg would have been a wholly unnecessary and unjustifiable procedure.

A considerable amount of experimental work has been undertaken in an endeavor to understand the manner in which these crucial tears and tibial avulsions take place. It would appear that they must be more or less clearly connected and that whether the one or the other takes place must depend upon whether the bone or the crucial ligament was the stronger or, what is more probably true, upon some circumstance whereby the one or the other was better guarded against the violence inflicted. Experimentation on the cadaver in an attempt to solve a problem of this kind makes no appeal to me, for in life there are both positive and negative factors entering into the production of traumatic lesions which could never be staged after death had ensued and rigor mortis set it and are, indeed, very infrequently staged during life. They should perhaps be given for what they are worth but this appears to me to be a very poor sort of evidence upon which to build up a theory.

Dittle, who had a case of crucial ligament tear lost the patient after amputation of the thigh. In addition to the injury to the crucials there was also a fracture through the spine of the tibia. The nature of the injury causing these lesions was known in this case and so, after the death of the patient, he undertook to reproduce the same injury in the other leg by repeating the trauma in the same manner as in the first instance, viz., with the leg in flexion and forced abduction. From all the reports of attempts at experimental production of crucial rupture it would appear that the outer defense of the crucials and the tibial spines is the internal lateral ligament and its muscular reinforcements. If this is seriously torn or sufficiently badly stretched, so as to permit of the procurement of a laxity leading to over-tension upon the crucials, we may find anything, ranging from a complete tear, to a partial rupture or merely a severe stretching, if the ligament is weaker than the bone or the application of the force has been in such a fashion as to provoke the tearing of the ligaments rather than a fracture of the tibial spine. The possibilities of over-stretching of the structures which make the knee-joint stable are familiar enough to those who have observed the effects produced upon some knees in the course of the treatment of hip disease with traction splints. It is evident that all ligamentous structures may be stretched if the force is applied gradually enough under the proper conditions. Again when the internal lateral ligament is torn in its deeper fibers and, as occasionally happens in these cases, thin plates of bone are pulled away from the internal femoral condyle when this ligament is stronger than the bone, then the possibility of abduction of the leg, when in full flexion, permits of the develop-

ment of rotation of the tibia to an extent which threatens the integrity of the crucials.

Interesting as speculations in respect to how these injuries are actually brought about may be, it is after all an academic question. Exact knowledge as to how it was done would not lead to the diminishing of even the number of instances of the accident. Therefore the interest in this partial review of the reported cases centers largely upon the methods of treatment employed by various observers and more particularly upon the outcome of these treatments. The earliest reported case is the one described by Godlee in 1888 which was a museum specimen procured from a patient whose leg was amputated by Erickson in 1873.

The following résumé of the literature is chronological.

MAYO ROBSON, *Ann. Surg.*, 1903, Vol. 37, p. 716. (Paper read at Clin. Soc. Lond., Dec., 1902.)

A 41-year-old miner was crushed under a landslide, sustaining multiple injuries from all of which he recovered at the end of 36 weeks except from that inflicted upon the knee. This was lame, weak and unstable. The tibia would stay in its proper relation with the femur only when it was held forward, immediately dropping back if left alone. It could be brought forward somewhat in front of the femur and there was also free lateral movement. Fluid in joint. At operation the joint capsule was injected and there was much effusion. Both crucials were torn across at their upper insertion and frayed out. As well as he was able, he reattached them to the synovial membrane as near as might be where they belonged. Catgut was used. At the end of a month of fixation passive and then active efforts were commenced to restore motion. Six years later he was seen by Robson's house surgeon who reported his leg as perfectly strong. He could walk without limp and was able to run. Worked 8 hours per day at his old work in the mines and only when he became very tired did he have any discomfort in the knee, and then only on the inner side. There was no abnormal mobility. Extension was complete; flexion a little limited after a right angle was passed with some crepitation and pain if forced flexion was attempted.

W. H. BATTLE, *Trans. Clin. Soc. Lond.*, Vol. 33, p. 232.

A woman of 50 had her leg caught between a station platform and a moving train and outwardly twisted. Admitted to St. Thomas Hospital, July 23, 1898, and discharged Oct. 8, 1898, with a leg capable of flexion to a right angle and ability to walk well. The ligaments of the joint seemed intact. There was evidence of rupture of the crucials and lateral ligaments and open operation was undertaken, after failure by manipulation to be able to secure a readjustment of the

bones, a fascial band was found to be obstructing and was divided. The anterior crucial was completely torn across and the posterior partially torn. The crucials and laterals were sutured with silk and the ligamentum patellae was also sutured as the joint had been opened by that route.

SIR ROBERT JONES, *Clin. Jour. Lond.*, 1906, Vol. 28, p. 51.

In this article Sir Robert treats of the internal derangements in practically the same way and based upon about the same material that he does in the article in the *Annals of Surgery* for 1909. There are no other reported cases or ideas regarding the condition.

Avulsion of the Spine of the Tibia. J. H. PRINGLE, *Annals of Surgery*, Aug., 1907.

Three instances on record at that time, viz., that of Dittle, Poncet, and one admitted in 1873 to the University College Hospital in London. In all three of these cases the lesion was discovered either after death or at amputation. Author's case: CASE I. Male, 36, admitted to Royal Glasgow Infirmary June 14, '03. A large, powerful man was knocked down by the shaft of a cart and the knee forced inwards. There was much bruising and effusion and the only abnormal mobility was in abduction at the knee. Question of crucial rupture was raised, as was that of rupture of internal lateral ligament. On exposure of the internal lateral ligament 10 days after entrance, there was no evidence that it was not intact. Under the anaesthetic, as before, there was no abnormal antero-posterior movement at the knee. The joint was then opened and it was found that the anterior crucial, still attached to bone, had pulled the spine of the tibia away from the head of the tibia. This was sutured with a little difficulty. He has been seen several times since and has a good result though a slight amount of abduction persists and in coming down stairs he occasionally has a little trouble.

CASE II. In 1902 Pringle saw an athletic young man, who 5 months previously had been injured in the knee at a football game, and since then there had been instability of the joint. There was great looseness of the joint without fluid when seen by Pringle and apparently about 25 degrees of abduction with the leg in full extension was possible. There was marked atrophy of thigh and calf. The tibia could not be displaced forward and no abnormal rotation was possible. However at operation there was forward movement of the tibia on the femur without rotation; no rupture of the internal lateral ligament but a tear of the anterior crucial which was reattached to the external condyle. Good recovery with restoration of stability and confidence together with the resumption of all athletic activities with very slight abduction in full extension. A second injury 3 or 4 years after

was productive of a severe strain without any permanent injury.

The author then proceeds to discuss crucial ruptures, citing first Dittle's case and then Robinson's. Dittle's case was caused by forcible abduction of femur with leg in flexion. The leg was amputated and avulsion of the tibial spine then noted. Patient died and Dittle was able to produce the same lesion in the other leg with some difficulty, experimentally, by applying the force as it had been applied in the production of the accidental avulsion.

Pagenstecher and Harrigschmeid have both produced this lesion and rupture of the crucials by blows upon the front or back of the head of the tibia. Pagenstecher was only able to rupture the anterior crucial from its femoral attachments. Hyperflexion and hyperextension are capable of most often rupturing the anterior and posterior ligaments respectively.

Pringle is of the opinion that flexion, abduction and rotation of the leg, when the pelvis is fixed, is the more common method by which the anterior crucial is ruptured and of the three, rotation is of the greatest importance. He further states that it is his belief, as a result of his experiments upon the cadaver, that when the anterior crucial is ruptured a greater amount of rotation (inward) of the tibia upon the femur occurs with the leg in complete extension and that under these circumstances the internal lateral ligament has been subjected to great stress and its deeper fibers have been torn, thus permitting of abduction of the leg when extension is complete, an impossible situation without rupture of the anterior crucial. In conclusion he decides that abduction in full extension means rupture of anterior crucial plus tear of deep fibers of the internal lateral ligament; that ability to push the tibial head backward with leg in flexion means posterior crucial tears, whereas ability to move the tibial head forward means anterior crucial tear when leg is in extension. He concludes that all joints with any of these phenomena present should be explored and that often, in this way only, can an accurate diagnosis be made.

SIR ROBERT JONES (*Annals of Surg.*) Dec., 1909 cites one case of fracture and backward displacement of a tibial spine, together with the crucial ligament attached thereto, and says he recalls no other case related in the literature. (Case IX in this series of reported cases.) His case was a 40-year-old man whose injury was from a bicycle accident. Effusion and inability to extend the knee. The anterior crucial was carried back with the tibial spine. Bone was removed leaving enough fibrous tissue to which to attach the anterior crucial and secure a fair functional result without power for complete extension. This operation was not done until 8 months after the accident.

In regard to the ruptured crucial she had op-

erated only one, in 1909. The anterior crucial was completely torn across and frayed out. Suture was by plication, not end to end, but in 8 months stability and mobility to the joint were secured. In this case 10 weeks after the accident, which resulted in a dislocation of the knee, there was inward, but no outward, rotation, and the tibia could be displaced forward when in extension. A second one in a boy of 15 with a dislocated knee (plus a necessary rupture of both crucials) he kept in fixation 2 months and obtained a good recovery. He believes that it is a not uncommon injury and is amenable to mechanical treatment with good results if this is kept up long enough.

S. ALWYN SMITH. *British Journal of Surg.*, vi, 176, 1918. Injuries to the Crucial Ligaments.

The writer makes a series of 9 cases the subject for a clinical report and discussion of the subject of injuries to the crucials. He comments on the fact that up to ten years previous to the time of writing very little had gotten into the literature on the subject. He refers to the experimental work of Högjög, Schmeid, Pagenstecher, and Little. Pringle's case of avulsion of the tibial spine (1907) and Corner's work on the surgery of the knee-joint (1914) are the subjects of reference. The writer, while associated with Sir Robert Jones, was struck by the fact that whereas intra-articular fractures were more frequent than was commonly supposed, many of them were connected with crucial ligament injuries and in almost as many there was no such injury to the ligament, though the trauma was to all intents the same. Oftentimes there would be a fracture of the tibial spine without crucial ligament injury. One of the purposes of the paper was to show the importance of stretched or strained crucial ligaments when associated with injuries to the semilunar cartilage, offering an explanation as to why the usual surgery of the semilunar injury was not as successful in individuals whose semilunar dislocation was complicated by crucial ligament tear.

He enumerates the supports of the knee-joint, particularly the muscles, the synovial and fibrous capsule, with its lateral and posterior reinforcements, also the semilunars and crucials. Each and every one of these is dependent upon the other to a certain extent. He also cites the mechanism by which each is aided to exert its protective action upon the joint; e.g., of the semi-tendinosus tendon in posterior crucial tears just as the sartorius is used in the anterior crucial substitution.

The results of his 9 cases have been in the main satisfactory though the results in two were bad. These were the earlier cases and may perhaps be due to imperfections in early technique.

ROBERT JONES and A. SMITH. *Brit. Jour. of Surg.*, 1913, i, 70. On Ruptures of the Crucial Ligaments of the Knee and Fractures of the Spine of the Tibia.

Though Pringle's case of tibial spine avulsion was the first reported as successfully stitched back, Richard Godlee, in 1888, described the first citation in the literature. This was from a case amputated by Erickson in 1873.

The authors do not wholly agree with Pringle in his explanation of the mechanism of avulsion of the tibial tubercle for they think it does not explain all the cases. They had seen and report 17 cases of injury to the spine of the tibia in 3 years. They describe the shape and size of the tubercles and the inclination of the intercondylar notch and call attention to the fact that osteo-arthritic changes in the spines cause sharpening of the tubercles and then state the signs that indicate rupture of the crucials and the chief indication of avulsion of the tibial spine.

A. PONCET. *Bull. et Mém. Soc. de Chir. de Paris*, 1875, i. Arrachement de l'épine du tibia à l'insertion du ligament croisé antérieur.

This is a record of a verbal report made by M. Despus from the Chief of the surgical clinic of the Hotel Dieu of Lyons. The anatomical material was demonstrated from the autopsy of a man of 50 who fell from a height and died as a result of a skull fracture. At the autopsy the surgeon in attendance, by pure accident, had the left knee-joint opened, though there was no evidence of external violence, and found the joint full of blood and the anterior crucial was observed attached to the spine of the tibia, which it had avulsed. Poncet thought such a lesion must be caused by torsion of the knee and might occur with very little evidence of its existence from the outside.

MEDICAL TIMES & GAZETTE, 1876, ii, 389. Separation of the Spine of the Tibia.

This article cites as rare, at this time, of the type of fracture of the tibia described by Prof. Poulsee of Bordeaux, as follows: An energetic cross-lord was ejecting a tenant whose legs "landed themselves backward." Someone gave the man a kick in the thigh which resulted in a bloody effusion into the knee-joint. Aspiration was followed by infection and amputation. Examination of the specimen showed that the torn portion of the anterior crucial ligament had detached itself from its lower origin and had pulled an oval portion of the head of the tibia off with it. The discovery of this condition led Dittle to try experimentally to repeat on the cadaver the kind of violence that had resulted from this sort of injury. The method employed consisted in the application of force in flexion, extension and rotation. In extreme extension the tibia gave way and if anything occurred inside the joint it was the posterior ligament that yielded. In over-flexion it was the anterior ligament that gave way but always remained attached to the tibia. This report is in *Centralblatt für Chir.*, No. 29. He refers then to Poncet's case and cites still another, now in

the Museum of the Univ. Coll. Hosp., London, obtained in April, 1873. This was exactly like Poncet's except that the patient was a boy of 11 years.

G. COTTE. Three cases of Restitution of the Crucial ligaments of the Knee. *Lyon Chirurgica*, Vol. 16, 1919, 586.

CASE I. A young man, 21, was thrown by the explosion of a shell while in service, the leg being in a position of forced flexion. He could not get up nor walk; great effusion immediately. Treated by immobilization and massage, passing through a number of hospitals until he finally fell into the writer's hands, at which time there was no pain or motion but a decided laxity both to antero-posterior as well as lateral motion. The forward movement of the tibia from a position where it was easily palpated in the popliteal space could readily be recognized. It also would appear that there was a rotation of the femur on the tibia. Open incision was resorted to and the anterior crucial was found ruptured. There were only two thin strands of fibrous tissue left to represent it. With Allen's perforator he tunneled both the tibia and the femur and passed a suture 3-4 mm. in diameter holding the two bones in close apposition, the suture being buried in the periosteal tissues. Silk was the material used supplemented by a few catgut sutures. A posterior splint was employed. This was removed on the 30th day and for the first time passive motion was practised. Seven weeks after the operation and at the time of leaving the hospital the result promised to be an excellent one, but when later he was seen after commencing to walk, the laxity and subluxation returned and the results seem not to have been as good as promised.

CASE II was a soldier who had ruptured a crucial (anterior). He was operated first for a fringe which though removed brought no relief. A second time he had the joint opened and the ruptured crucial was found and repaired with a strip of fascia lata with no better result apparently, for there was great pain, effusion and locking of the joint. A third arthrotomy was performed to arthrodesis the joint and it was then discovered that he had a dislocation of the semilunar which was responsible for the symptoms following the two previous operations and that the crucial repair was satisfactory. The patient refused to have anything done other than an arthrodesis.

CASE III. This patient was a young man who had a ruptured anterior crucial and a dislocation of the semilunar. He was kicked by a horse and his symptoms were all those of semilunar dislocation. The operation was performed after exposing the joint through a U-shaped incision. The anterior crucial was repaired by suturing a piece of fascia lata in its place, removing the torn meniscus of the semilunar,

and restoring the patellar tendon. He was enough better so that he was accepted for military service whereas he had been refused before.

His belief is that rupture of the crucials alone is a rare accident; that the lateral ligaments are commonly ruptured along with the crucials and that not infrequently a meniscus goes with them. His confrère, Tarnaviev, holds an opposite opinion and he reported cases of the same sort in this same journal.

MEDICAL RECORD, Vol. 96, 1919, p. 948.

There is a discussion occurring in the New York Academy of Medicine at which a paper was read by Dr. W. A. Sherwood, based upon 400 cases of knee-joint injury, occurring during the period of military preparedness at U. S. Army Hospital No. 1. There were several cases of ruptured crucials and fractures of the tibial spines. The paper has not yet been published or at least come out in the literature. The meeting of the Academy at which it was read was that of Oct. 3, 1919.

PARIS CHIRURGICAL SOC. DES CHIRURGIENES DE PARIS, xi, 1919, pp. 53 & 352.

1. Rene Le Fur. Primary suture of crucial with recovery.

Had previously reported 6 cases with good results from operation. The case he now reports, 26 hours after the injury, was one of severe injury from a bullet in the knee, with cutting away of the crucial and injury to the superior articular support of the tibia. Operated immediately, very minute care being given to the sterilization of the joint with ether. Three months after the operation, consisting of disinfection, repair of crucial and a partial resection of the articular surface of the tibia, it was impossible to see any difference between the sound and the wounded knee so far as function was concerned. The incision was closed without drainage, which is a menace to any joint, the writer claims.

2. Henry Fay. Primary suture of ligament of knee.

Report of a shell explosion as a result of which the knee-joint was opened by a shell fragment which imbedded itself in bone and ruptured a crucial.

Complete sterilization with ether one-half hour after injury and repair of rupture with perfect functional result.

E. W. HEY-GROVES, *British Journal of Surgery*, 1919-20, 7, 505.

Hey-Groves says that all the crucials he has seen have been so destroyed that there was no question of suturing them. He believes that it is justifiable to explore a knee-joint through a full exposure to secure opportunity for observing the entire joint if for no other reason than to enable a diagnosis to be made and he feels that many of the obscure cases may be diagnosed

and treated in this way. Mayo Robson appears to have been the first to undertake the repair of a ruptured crucial though Battle published a case first. Gaetjes reviews the literature to 1913 and found 33 cases which, with his 7, made 30 in the literature up to that time, and he included among these Mayo Robson's. Of these, 12 were subjected to an open operation. In 5 an attempt was made to effect a repair and in the 5th it consisted in the removal of bone torn off by the ligament. In 1913 Robert Jones and A. Smith reported a number of cases of fracture of the tibial spine some of which were associated with rupture of the crucial ligaments. In 1917 the author reported an operation for the repair of these ligaments by means of fascia or tendons. During the war the rupture of these ligaments was quite common and in the 3 years before the publication of this paper the author had operated 14 cases. He then describes the anatomy of the crucials at length. Most of his cases occurred as the result of being knocked down or buried by shell explosions. He then describes under diagnosis the symptoms and physical signs, the balance of the paper being a description of his tunneling operations through the internal condyle for rupture of the anterior crucial and the external condyles for rupture of the posterior crucial with the introduction through the tunnel of a portion of the gracilis and semitendinosus tendons in the latter.

As to the methods of getting at the ligaments for purposes of repair, he feels that the method of dissection and removal of the tibial tubercle ($1\frac{1}{2}'' \times \frac{3}{4}'' \times \frac{1}{2}''$ of bone) and reflecting it back, dissecting carefully so as to preserve the tendons on the inside and the ilio-tibial band on the outside is the best. The advantage of this over Alwyn Smith's median patellar incision, is that in this method it is not possible to give the right inclination of the new ligament, which should be downward and forward in the case of the anterior crucial and downward and backward in the case of the posterior, though it is true that this direction is more nearly vertical than that of the anterior crucial.

His cases were all of rather recent date, so that he cannot report end-results, but so far as he can, in the 14 cases, 4 showed no benefit, 4 were benefited to some degree; 4 were cured to such an extent that they could return to active duty in civil life without the use of a splint that he makes them all wear when they begin to walk. Two had been operated upon only two months before publication of the paper.

Fracture of the Tuberosity of the Tibia. Report of 3 Cases. JAMES W. SEVER. *Jour. Am. Orth. Assn.*, May, 1916, xiv, 299.

Sever reports 3 cases, one from an automobile accident and two from falls. He was unable to offer any explanation from the study of these cases as to how the force that caused them was

applied. He feels that two of his cases in addition to the tibial tuberosity injury had rupture of the anterior crucial.

CASE I. (Sever) Patient was a young woman who was knocked down by an automobile and right knee injured. Taken to hospital and her x-ray showed she had fractured the base of the external tuberosity of right knee about two-thirds of the distance from its anterior border. There was some downward and outward displacement. She was treated with a cast. The end-result was not a perfect knee because there was some knock knee and a weakened joint hindering her from using the leg as freely as she would like.

CASE II. (Sever) A steward, of 59 years of age, fell four ft., striking on knee. Wore cast 2 mos. and then a caliper splint for 2 mos. Seen by Sever 2½ yrs. after accident, when he could not use his leg well enough to do his former work. Could not walk without crutch; leg was weak and he tired easily. Moderate knock knee on affected side, with increase of abduction. About the external tuberosity there was bony thickening. X-ray showed fracture through external condyle of the tibia, extending into joint and also that the tuberosity of the tibia had been injured and slightly displaced. The slope of the external articular surface of the tibia had been altered. This evidently caused joint strain, which was the basis of his symptoms. There is not in this, nor was there in Case I, any restriction to complete extension. Sever thinks that by balancing the weight over "Thomas heels," relief can be brought to symptoms.

CASE III. Male, 45, fell 60 ft. six months before Sever saw him. He had multiple injuries. For 2 mos. he wore a ham splint on the leg with the affected knee. There is thickening about the internal tuberosity and a slight ridge where the upper fragment has slipped forward. Leg can be fully extended, but flexed only to right angle. Functionally the result is good. X-ray shows the fractures through the condyle, the head of the fibula and the head of the tibia.

J. J. KURLANDER. *Surg., Gynec. & Obst.*, 1915-1920, 179. Fracture of the Spine of the Tibia.

A single case is reported with reference to the work of Pringle and Godlee in 1907 and 1888 respectively. Male, 19, fell in 1913. While jumping from a wagon he landed in such a way that his leg flexed suddenly and struck his knee on the curb. He could not rise and could not extend the leg. Great swelling, pain; x-ray said to have been negative. A later x-ray showed a transverse fracture through the spine of tibia. He made a complete recovery under the use of plaster cast in full extension. Quotes two of Sir Robt. Jones' cases and refers to the possibility of operation in certain instances, but advises against it unless fixation fails.

Same author later, in *Jour. Am. Med. Assn.*, Sept. 10, 1921, pp. 855, adds two more cases and a fuller discussion of the literature. This was in a paper read before the A. M. A., orthopedic section, at Boston, June, 1921.

His two additional cases were caused by violence from falls. In one case in a woman of 50, when she fell on the stairs, her knee being flexed and abducted strongly. There was no sign of crucial ligament rupture, but there was too much abduction of the tibia on the femur, due to internal lateral ligament tear. X-ray showed avulsion of the tibial tubercle. He lost sight of this patient.

The third case was a 25 yr. old man whose fall caused him to violently hyperextend the knee. Was seen 4 mos. after injury by Kurlander when the chief complaint was of locking the knee, causing pain. There were a few degrees of limitation in motion in flexion and extension. There was no sign of crucial ligament tear. X-ray showed a crack through the tibial spine. He reviews the literature available.

FOSDICK JONES. Fracture of Tibial Spine. *Col. Med. Jour.*, Aug., 1920, pp. 217.

The author reports one case and reviews the bibliography. He refers to the cardinal symptoms of this injury as excruciating pain; great swelling within a few hours; inability to extend and flexion of from 15 to 35 degrees. Advocates conservatism in treatment and gives good prognosis under careful management.

His own case was that of a strong, athletic young man. Left leg was caught between the forward bumper of his car and the garage door, the force being directed against the inner side of the left knee. Could not flex or extend leg; had great pain and extensive effusion within an hour. Pain continued for 5 days and was over internal tuberosity of tibia; there was very little motion and attempts to secure it were very painful. There was an oblique fracture of the tibial spine, with displacement backward of upper fragment. Foreible extension and a cast were applied and continued for 9 weeks. Motion has increased until at date of reporting case full extension and flexion to 95 degrees were possible without lateral or antero-posterior displacement.

At this meeting 6 other cases were shown by x-ray, occurring in the practice of other Colorado surgeons, all showing fractures of the tibial spine.

CONCLUSIONS.

The keynote of the experience of the most careful observers seems to be that ruptures of crucial ligaments are not as serious affairs as at one time they were credited with being. Very serviceable joints may be expected after injuries of this nature and the operative methods employed may be counted upon to restabilize the joints with very little surgical risk. It would

not appear that in the majority of instances the conditions call for the tunneling operations and transference of muscles or transplants of fascia. Through the median patellar incision the opportunity to deal pretty directly with the crucials enables one to repair them or bridge them so that they repair themselves. Protection with a "cage" splint for several months after walking is commenced should be insisted upon.

So far as the treatment of avulsions of the tibial spines are concerned, my own experience might of course be wholly deceiving. It was sufficiently convincing to me, and from what I can learn about them in the reported cases, my impression has been borne out by the experience of others, viz.: that they should be treated conservatively by a cast with the leg in extension.

One final impression that such thought as I have been able to give to this subject has left upon me is that the probable reason for the comparatively good functional results that follow upon injuries that theoretically seem as though they were certain to be more or less serious, is that the contours of the articular surfaces of femur and tibia are not disturbed in the ligamentous tears. If they become distorted motion is lost and function is impaired, but when they are spared from injury the repair of these structures ensures a very considerable and generally fairly complete restoration to function.

An arthritic patient who lies abed for a long time with legs in slight flexion or complete extension will square off his condyles and subluxate his tibiae to such an extent as to completely incapacitate him even before he has eroded his cartilage or injured his capsule or ligaments enough to produce an incapacitating arthritic condition. If such osseous distortions may be avoided, there is scarcely any limit to the amount of legitimate optimism we may entertain as to the possibilities of repair and restoration of function in a knee-joint.

COMPARATIVE STATISTICS ON PHYSICAL EXAMINATIONS OF PUPILS OF THE BOSTON PUBLIC SCHOOLS FROM DECEMBER 1, 1915 TO JUNE 30, 1922.

BY WILLIAM H. DEVINE, M.D., BOSTON.

Director of Medical Inspection, Boston Public Schools.

There is a law in Massachusetts requiring annual physical examinations of school children. It is surprising the lack of knowledge that exists among parents, educators, and even physicians in regard to the requirements. When unreasonable parents protest, they are surprised to learn that the examination is compulsory, and promptly yield to argument when informed of this fact. Since the writer has had charge of medical inspection in the Boston public

schools, all have submitted to the annual examination; no child is excused.

The law requires that children shall be separately and carefully examined every school year, and a written notice of any defect or disability sent to the parent or guardian. In Boston, it is required to complete these physical examinations before December first. The wisdom of this rule is obvious—it admits of prompt and timely treatment.

In some states a law which allows the family physician to make examination has been tried. I cannot see any advantage to this. It would be impossible to obtain the impartial and uniform records by this method as by examination of school physician.

All children are weighed and measured at time of physical examination and record of weight and height is made on physical examination record card. Outside wraps, such as coats, sweaters, etc., are removed before weighing. Children from the kindergarten to the sixth grade, inclusive, are stripped to the waist for physical examination.

In addition to the regular routine examination, the school physician examines all children who require it as often as necessary.

Physical examinations of girls in high, Latin, and Normal schools are made in the presence of the instructor of physical training, the teacher, or matron. Physical examinations of pupils assigned to open-air classes are made in September and re-examination in February.

Every child between the ages of fourteen (14) and sixteen (16) years, who presents the required promise of employment card, and other evidence required by law, to the school physician assigned to the office for the issuance of employment certificates, is examined by the physician who certifies whether or not the child is sufficiently sound in health and physically able to perform the duties indicated on the card. (See Table I.)

Children in open-air classes and in malnutrition groups are weighed and measured monthly and record is kept on special cards.

Special physical examination of candidates for the Normal school are made by the school physicians in January and June preceding graduation from high school. Report on each examination is sent to the Director of Medical Inspection. Applicants for admission to Normal school may be rejected for any of the following causes:

- Communicable diseases, *e.g.*, tuberculosis
- Defective vision.
- Defective hearing.
- Epilepsy.
- Chorea.
- Chronic bronchitis or asthma.
- Affections that are
 - (a) unsightly, *e.g.*, chronic skin diseases.
 - (b) offensive in nature, *e.g.*, ozena and allied diseases.

TABLE 1.—REPORT ON PHYSICAL EXAMINATIONS FOR EMPLOYMENT CERTIFICATES
NOVEMBER, 1915, TO JUNE 30, 1922

	11-0-1915 to 8-31-1916	9-1-1916 to 8-31-1917	9-1-1917 to 6-30-1918	7-1-1918 to 6-30-1919	7-1-1919 to 6-30-1920	7-1-1920 to 6-30-1921	7-1-1921 to 6-30-1922
Number of children examined	10,174	17,577	16,722	19,810	18,711	11,581	8,281
Boys	6,121	10,785	9,585	10,725	10,265	6,460	4,447
Girls	4,053	6,792	7,137	9,085	8,446	5,121	3,834
Number of children without defects	4,986	8,041	7,116	9,064	8,418	5,798	4,476
Number of children with defects	5,188	9,536	9,606	10,746	10,293	5,783	3,805
Total number of defects	6,603	11,846	12,906	13,239	12,872	7,144	5,011
Number of children recommended for certificates	9,969	17,103	16,088	19,470	18,048	11,049	7,839
Number of children not recommended for certificates	205	474	634	340	666	532	442

Any disease or condition which the school physician certifies and deformities that would manifestly interfere with physical activity, are also causes for rejection.

The results of annual physical examinations in public schools with re-examination of special cases is one of the most prophylactic features of public health measures. The timely treatment of diseases; the prevention of the spread of communicable diseases, *e.g.*, pulmonary tuberculosis, etc.; the discovery of defects qualifying children

for open-air and other special classes, are some of the advantages that are evident in addition to the many ailments discovered, and referred to family physicians and clinics.

It would be very difficult to carry out physical examinations efficiently without the assistance of the school nurse in the elementary school and the physical training instructor or matron in the high schools. Parents of girls in high schools and upper elementary grades object to examinations unless carried out in this manner.

TABLE 2.—COMPARATIVE STATISTICS OF PHYSICAL EXAMINATIONS OF PUPILS OF
BOSTON PUBLIC SCHOOLS FROM DECEMBER 1, 1915, TO JUNE 30, 1922

	1915-16	1916-17	1917-18	1918-19	1919-20	1920-21	1921-22
Total number of pupils examined	99,802	104,287	104,762	100,564	105,193	107,664	113,780
Total number without defects ..	30,781	38,318	43,128	43,328	46,065	51,158	56,262
Total number with defects	69,021	65,969	61,634	57,236	59,128	56,506	57,518
Defects as follows:							
Defective Nasal Breathing:

Totals	59,307	10,010	38,152	35,041	35,035	31,345	35,510
Defective Teeth	56,750	55,638*	50,507	41,531	45,567	43,685	41,783
Grand Totals	116,057	95,648	88,659	79,572	80,602	75,030	77,293

*During the year 1915-16, and from October 1, 1916, to January 1, 1917, defective teeth were classed as primary and secondary. In some instances, if a pupil had defective primary and defective secondary teeth, it was recorded as two defects instead of one. In order to avoid duplication of defects, it was thought advisable to record defective teeth without regard to whether they were primary or secondary. This method was adopted commencing January 1, 1917, and precludes comparison for the two years.

The number of cases of cardiac disease in the Boston public schools remains practically the same for the past six years. Naturally it would remain about the same or increase from year to year, as children are not excluded for this disease. The figures in the preceding report have been compiled from the examinations of forty-nine (49) school physicians, and the fact that these do not vary to any great extent in the past six years is some evidence of the accuracy of the observations of the medical inspectors.

All cardiac cases are followed up by the school nurses in the same manner as other defects—the homes of the pupils are visited and parents instructed relative to care. The teachers are also notified in order that these pupils may receive special consideration.

The total number of home visits by nurses during the school year just closed was thirty-five thousand, six hundred twenty-one, (35,621) for all cases. It is impossible to state how many of these visits were especially for heart disease but the large number of nurses' visits indicates that the cardiac patients were not neglected.

About two per cent. of the children in school populations are found to have some cardiac disorder. In the Boston public schools about 1.25 per cent. organic and about 2 per cent. functional.

For obvious reasons the causation is uncertain. Only by careful medical supervision and follow-up work can the etiology be traced with any degree of accuracy. Rheumatism, infectious diseases, defective teeth, tonsils, and other local conditions have assumed an important place in the etiology of cardiac lesions, although I believe the importance of the minor ailments in the causation of morbid conditions of the heart is exaggerated. I have known many cases where the removal of teeth diagnosed as defective by x-ray have been removed with the idea that it would improve or cure the heart. Practitioners should proceed cautiously in these cases as sometimes the shock and impairment of health due to loss of teeth is an injury rather than a benefit. The dentist and nurse have been too susceptible to the well-meant propaganda of ardent enthusiasts who can see dental defects as the cause of many cases.

I am not disparaging defective teeth or infected tonsils as a cause for heart disease and the proper treatment of these conditions is advocated. The early and thorough physical examination of the school child has been a great step in progress in cardiac prophylaxis. The general practitioner should examine the patient in routine manner when he attends the patient for tonsillitis, diphtheria, scarlet fever, rheumatism, chorea, and other diseases which are known to cause cardiac disease. Not only should he make frequent examinations during illness but after convalescence, if possible, and note the condition of the heart when the patient is discharged.

The following is the list usually given by medical authorities as etiological factors in heart disease: tonsillitis, acute rheumatism, measles, pneumonia, diphtheria, chorea, pertussis, scarlet fever, syphilis, influenza, bronchitis, typhoid, nephritis, otitis media, chicken-pox, carious teeth.

No endeavor is made to give the relative frequency of the list enumerated above. Osler stated that endocarditis is found post mortem more frequently in chorea than in any other disease.

The prevention of heart disease offers a great field in prophylaxis. The timely notification of parents is an important step in prevention procedure. There were many cases where school notification was the first intimation to parents that a child had cardiac disease. Its early detection in the schools; longer rest in bed after contagious diseases; the proper care of the teeth and removal of diseased tonsils and adenoids should tend to reduce the number of cases.

The prevention of heart disease has been treated in a masterly manner by Dr. Haven Emerson in the Shattuck Lecture, June, 1921. Those who are interested are referred to this gem of medical literature. He states:

"My objective will be to persuade you that it is within the realm of possibility, within the reach of present-day medical and social knowledge and resources to make as much reduction in sickness and premature death from heart disease as may be obtained by teaching, by diagnosis, by organized medical services in the control of tuberculosis. What is important to obtain but not yet available is a careful clinical and pathological study of the age of infection or onset of valvular or other organic heart disease."

To summarize the principal points in the prevention of heart disease, the writer would recommend:

1. Examination as soon after birth as possible.
2. Prompt notification to parents of any cardiac defect with recommendation for treatment.
3. Special care during and after convalescence—more rest in bed—freedom from excitement, etc., during the stage following acute diseases; examination of heart when discharging patient.
4. Prevention of rheumatism and other diseases causing the ailment. This should include proper care of the teeth, removal of adenoids and tonsils if necessary, etc.
5. The prevention of communicable diseases.

The following is a quotation from the Acts of 1908, Chapter 181:

"In each of the subjects of physiology and hygiene special instruction as to tuberculosis and its prevention, shall be taught as a

regular branch of study to all pupils in all schools which are supported wholly or partly by public money."

The Director of Medical Inspection has reason to believe that that instruction has been conscientiously carried out in our schools.

Important points on prevention have been duly stressed by the physicians and nurses of this department in their instructions to teachers and pupils, and pertinent circulars have been distributed. These activities have been promoted by the earnest coöperation of the school force. The Director of Medical Inspection desires to emphasize the importance of continuing this good work.

The figures on tuberculosis as shown in this report may appear small but it must be taken into consideration that children with pulmonary tuberculosis are excluded from school and that naturally the number of cases would not increase at the same rate as cardiac and other diseases.

The tuberculosis leagues, Massachusetts and Boston, the tuberculosis clinics, the State and City Health Departments, the medical profession, school physicians, and school nurses have nobly coöperated in the prevention of tuberculosis.

CHRONIC INTESTINAL INDIGESTION DURING THE SECOND AND THIRD YEARS OF CHILDHOOD.*

By LEWIS WEBB HILL, M.D., BOSTON.

It is not generally realized that children during the second and third years need as careful dietary supervision as they do when they are on an exclusive milk diet, and many mothers who would not think of attempting to feed a small infant without medical advice, and who would take the utmost pains with milk modification, let the child eat practically anything he wants after he has begun to take solid food. It is this carelessness that is responsible for not a few of the cases of chronic intestinal indigestion which we all see so frequently; the rest of the cases follow an acute attack of fermentative or infectious diarrhea, which can likewise be largely prevented by proper feeding. Let us consider briefly the feeding of normal infants during the last quarter of the first and the whole of the second year.

There is at present a tendency to feed too varied a diet at too early an age, such as large amounts of green vegetables, potato, and eggs to infants even before they have reached the end of the first year. In many cases this does no harm, but in others it causes severe digestive disturbances, which may take months to repair.

My own practice is to begin semi-solid food, such as oatmeal, farina, or zwieback soaked in

milk, at the eighth or ninth month. At this time chicken or lamb broth with rice may also be added, and a small amount of apple sauce or prune sauce if the baby is constipated.

At the end of the first year the baby should be taking daily about a quart of whole milk, some starchy food such as cereal, zwieback, rice or dry bread, twice a day, a little soup or possibly beef juice, orange juice, apple sauce or prune sauce. This is a quite sufficient diet, and the average normal baby does well on it. At about the fourteenth or fifteenth month strained vegetables such as spinach, carrots or tender string beans may be added, and potato may also be added about this time.

Potato starch is for some reason more likely to cause digestive disturbance than almost any other kind of starch, and although we have all seen babies of a year old, or even younger, thrive while taking large amounts of it, in general it is best withheld until the fourteenth or fifteenth month. Potato and green vegetables should not be given on the same day at this time; it is usually best to give potato one day, a green vegetable and rice the next day. It is well not to give too much of the same sort of starch on the same day; if oatmeal is taken for breakfast it is best to use macaroni, zwieback or bread and butter for supper.

Soft-boiled or coddled eggs may be begun at sixteen months, a couple of spoonfuls at a time, and gradually increased until a whole egg is taken every day. Eggs do not agree with all babies, and if such is found to be the case in any individual instance, it is best to omit them temporarily from the diet, and to start them again in another month or two. Some babies who cannot take the whole egg can take the yolk, hard boiled and grated in with the vegetable or potato. Meat is usually begun at about two years, the best meat to use being chicken, lamb chop or crisp bacon. It is not common for meat to cause digestive disturbance, and I have a suspicion that it might probably be begun considerably earlier in small amounts, without doing any harm. No raw fruit should be given to children under four or five years of age; in this part of the country (North Carolina) all milk fed to babies and small children should be boiled or pasteurized at all times of the year, and it should not be Jersey or Guernsey milk. The child should not be fed between meals, and he should be made to eat every new article of food as it is offered, unless it actually seems to disagree with him.

It is just as easy to feed children correctly as incorrectly, and it will be found that the vast majority of children do well on the general plan outlined above. I have spoken somewhat dogmatically in order to be clear and to save time, and realize that very likely some pediatricists would criticize the above plan of diet.

So much for a brief résumé of the principles

*Read at the annual meeting of the Medical Society of the State of North Carolina at Winston-Salem, April 26, 1922.

of feeding a normal child; let us now consider chronic intestinal indigestion.

For practical purposes this may be divided into two groups: the mild cases, and the severe ones. In the mild cases there is a certain amount of indigestion, due almost always to overfeeding with fat or starch, but there is no far-reaching general nutritional damage, and the indigestion is not in most cases hard to correct. In the severe cases there is present a marked and a long-standing indigestion, which has continued so long that severe damage to nutrition has been brought about, which may take years to correct.

The Mild Cases.

A child of two or three years is brought to us because of failure to gain, poor color, occasional undigested stools, and probably a certain amount of abdominal discomfort. Upon examination we find a child who is somewhat underweight, who is pale, whose flesh is rather flabby, and whose abdomen is likely to be somewhat enlarged. There is nothing else found upon physical examination. Careful observation of the bowel movements is here of the utmost importance, for by knowledge gained from this source, together with a consideration of what the child is eating, it is not difficult to find out what element or elements of the diet he is not digesting. The trouble is usually due to overfeeding with either starch or fat, and the stools vary according to which element is at fault. In the starch cases they are likely to be rather large and mushy, of a brown color, and with a peculiar half sour, half foul smell, which somewhat resembles that of a pigpen. If fat is at fault they are likely to be rather light colored and not so large or so mushy as in the first case. Microscopic examination is of considerable importance, and without it, in this type of case, one is working in the dark. One may find a large excess of either fat or starch in the movement, and make one's diagnosis accordingly. Anything more than the very smallest amount of undigested starch is abnormal, but it must be remembered that there is normally not an inconsiderable amount of fat present. It is not possible to treat these cases successfully, unless one knows which food element is at fault; this is accomplished by a study of the diet of the child and by examination of his bowel movements.

The treatment of the mild cases is not difficult, and is most satisfactory. It consists simply in considerably reducing the amount of the offending element in the diet. In the mild fat cases it is usually enough to instruct the mother to pour off all the cream from the top of the child's milk, and to omit also butter and bacon. In the starch cases a reduction in the total amount of starch taken in, and a limitation to the more easily digestible forms is all that is required. Potato should always be with-

drawn and the green vegetables should be considerably restricted. Rice jelly, crisp toast or zwieback are, probably, as easily digestible as any form of starch. Rice can be given in the morning, and possibly again at noon, the zwieback at night. The rest of the diet would consist of milk, eggs, meat; essentially, then, the diet of a normal child with the starch somewhat restricted both as to quality and quantity. Under this régime the abdominal distress should soon disappear, the stools should improve and the child should begin to gain in weight.

Following is a typical case of starch indigestion of rather mild degree.

H. S. was first seen at fourteen months on account of failure to gain, and undigested bowel movements. She had been breast fed up to eleven months, and was then put on whole milk, cereal, broth, baked apple and baked potato. She takes one small potato every day, and likes it the best of anything in her diet. She weighed 21 pounds 8 ounces at one year, and has not gained since. Her stools are always rather large, and somewhat loose; today she has had three foul, mushy ones. Physical examination showed nothing remarkable except a somewhat distended abdomen, and a rather flabby condition of the flesh. The stool was large, mushy and rather foul. It was brownish green in color, and contained a good many small masses which looked like pieces of undigested potato. Microscopically it showed innumerable granules of undigested potato starch. This child was put on the following diet:

Breakfast: Milk, 8 ounces, plus oatmeal or farina.

Lunch: Milk, 8 ounces.

Dinner: Soup with rice, and one or two tablespoonfuls of well-strained carrot or spinach, junket, milk.

Supper: Macaroni, or zwieback and milk.

In a very few days her stools had improved, and about this time the grated yolk of a hard-boiled egg was added to her diet. She did very well right along, was kept on this diet for about three months, and potato was not added to her diet again for another three months. She is now about four years old, and handles potato and all other starches without difficulty.

The very severe cases are different. This condition, which we call severe chronic intestinal indigestion, is called by the English the "Coeliac" or the "Mucous" disease, and the late Christian Herter of New York, who was much interested in it, called it "Intestinal Infantilism."

It is in reality a late stage of the condition of mild indigestion that we have already described, where the process is of such duration and severity that severe nutritional damage has resulted. It usually begins during the sec-

ond year, but may be seen in children somewhat older. It is very likely to follow an acute attack of diarrhea, or may come on more insidiously. The chief thing about it is the extreme impairment of nutrition. The abdomen is very large, so much so that the disease is not infrequently mistaken for tubercular peritonitis. The face is sharp and haggard, the skin loose and inelastic without any subcutaneous fat, the extremities frail and weak, often so much so that the child cannot walk. The stools, which form a very important part of the picture, vary at different times. They may be large and formed, rather light in color; this type of stool contains a large amount of fat, and is likely to be seen when the diet contains a considerable amount of this element, as would be the case if the child were taking whole milk.

At other times the stools may be very mushy, unformed, and may show large amounts of undigested starch and cellulose, both macroscopically and microscopically. This type of stool is seen if the child has a considerable incapacity for starch, and if much starch is fed. There will also usually be occasional periods of diarrhea, when the stools are very loose and watery. During these periods they will usually contain large amounts of mucus, sometimes more mucus than actual fecal substance. The stools always smell very badly, no matter what sort of diet is taken. If starch and sugar are being fermented they will usually smell sour, and will react acid to litmus paper; if a considerable amount of protein is taken, they are likely to be very foul, and alkaline. Vomiting is not ordinarily present, but may be in some cases, and is a most troublesome symptom. The child is very much stunted in growth, both as regards height and weight, and a child of three years may weigh as little as 15 or 20 pounds. The mentality is, however, unimpaired. These children are almost always alert mentally, but are likely to be of a rather peevish disposition. Rickets is occasionally associated with the condition, but not frequently enough to be of any significance. What is the cause of the condition, and what conception shall we take of it in order to formulate a basis of treatment? There is no evidence to show that it is primarily an organic disorder of one of the larger digestive glands, such as the pancreas or liver; there is no evidence to show that the essential etiological factor is a primary inefficiency of any of the digestive ferments, and all students of it have tried the administration of various of these ferments without success. At autopsy there are no especially noteworthy or characteristic lesions found except a rather thickened and irritated intestinal mucosa. Probably the best conception to take of this condition is that it is brought about by a chronic infection of the intestinal contents (note I do not say intestinal wall) with organisms which should not be there, and that the small intestine, which should nor-

mally be relatively free from bacteria, is flooded with an alien bacterial population, which hinders the normal process of digestion that should go on there; this bacterial population lives upon the food within the digestive tract, and the irritating products resulting from bacterial decomposition of the food set up a chronic inflammatory condition of the intestinal mucosa, which in its turn probably hinders digestion and absorption. The late Christian Herter, who was as close a student of this condition as anyone, believed that the bacillus bifidus, which is so commonly and normally found in the stools of breast-fed infants, and an organism which he called bacillus infantilis, were the two most common offenders. For us the name of the organism or organisms which are present is not of especial significance, as long as we understand that they are almost always organisms which seem to thrive upon starch, and which do not readily attack protein. It is not certain whether the fat intolerance practically always found in these cases is caused by direct bacterial fermentation of fat or is secondary to the original carbohydrate decomposition.

This, then, is our working conception of chronic intestinal indigestion, and is probably not far from the truth. In a word, therapy consists in reducing or entirely removing from the diet the food or foods upon which the especial group of organisms which are present in any individual case, seems to thrive. By so doing, by declining to furnish a suitable culture medium to the abnormal bacterial flora, it tends to die out, and normal conditions are gradually restored.

We have four foodstuffs to consider: fat, sugar, starch, and protein.

Protein is very well tolerated, and a diet very high in protein is always advisable. A moderate amount of sugar, such as would be contained in milk, is usually tolerated and often very much more than this. Starch is hardly ever tolerated except in small amounts, and the very severe cases usually do better without any starch. In severe cases we have before us, then, the problem of nourishing a child on sugar and protein, with as high calorie a diet as possible, as these children need more calories than the normal child, before they will gain.

It is not easy to withdraw all starch from the diet, as the normal child depends so much on this foodstuff to furnish him calories.

Milk forms the basis of the diet, and lactic acid milk is usually better tolerated than sweet milk. This should be fat free, and if the child will not take lactic acid milk, boiled fat-free sweet milk may be used.

Whereas one would not feed a normal child over a quart of milk a day at the most, it is desirable to feed these children as much milk as possible, so that certainly as much as 48 ounces daily can be used, and possibly more.

If the child has a good sugar tolerance,—and very many of these children do,—sugar is advantageously added to the milk, and is a very valuable foodstuff, as it has a high caloric value, and is easily assimilable. Sugar is best given in the form of corn syrup, as originally advocated by Marriott. Corn syrup consists of glucose, maltose, and suerose, and is a very easily assimilable mixture of carbohydrates. One ounce by volume contains 33 grams of carbohydrate, and furnishes 136 calories. I gave one child nearly five ounces daily, thus furnishing about 600 calories by means of the syrup alone. Usually it is best to start with about two ounces a day, divided between the different feedings, and then to work up, if possible.

Meat is the next article of food upon which we have to depend, and although it does not furnish so many calories as does the syrup, it is very satisfying, and adds bulk to the diet.

A child of three years often will take and digest as much as six rounded tablespoonfuls of meat a day, and, contrary to the usual idea that meat is difficult of digestion, these children are able in most cases to digest it better than anything else. The white meat of chicken is the best meat to use, as it contains less fat than most other meat. Two other articles of food which are of value are cottage cheese, and muffins made from casein flour.

Cottage cheese is familiar to most housewives, and is made by adding a teaspoonful of essence of pepsin to a pint of warm milk. This is allowed to stand until it has "set," when the curd is broken up, and separated from the whey by straining through cheesecloth. It is then lightly salted and broken into fine granular crumbs. It consists almost entirely of casein, and a pint of milk will furnish about three rounded tablespoonfuls of cheese, which contain 60 calories. After a while a child learns to like this, and will usually take 4 or 5 tablespoonfuls daily without trouble.

Casein biscuits may be made from starch-free diabetic flour, the one I have used being "Diaprotein." It consists almost entirely of casein. These biscuits are rather dry, and not particularly inviting as to taste, but most children like them. The best way to give them is to break one in small pieces, and moisten it with a little milk. The average child of three years would take 5 or 6 of these a day.

Made according to the usual recipe, each muffin contains about 65 calories. The usual recipe calls for bacon fat; if this is left out, the caloric value is considerably less, and each muffin would contain only about 25 calories.

The cottage cheese and muffins are more or less interchangeable, being both made up largely of casein, and if one is used, the other probably would not be. As a general thing most children like the muffins better than the cheese. Let us recapitulate a moment and see exactly what

a child of three years, weighing 20 pounds, might take on this plan of diet.

18 oz. fat-free milk	= 480 calories
2 oz. corn syrup	= 272 calories
6 rounded tablespoonfuls chicken	= 150 calories
6 Diaprotein biscuits	= 380 calories
	<hr/> 1282 calories

This gives a total of about 1280 calories, or between sixty and sixty-five calories per pound of body weight; a rather ample diet. The following table of approximate food and caloric values may be found of service.

MILK.

	F	C	P	Cal.
8 oz. fat free	= 0	11	9	80
8 oz. skimmed	= 2	11	9	100
8 oz. whole	= 9	11	8	168

CHOPPED CHICKEN.

		F	C	P	Cal.
1 rd. tbsp.	= 15 gm.	= .60	4.8	25	
1 level tbsp.	= 10 gm.	= .40	3.2	16.8	
1 heaping tbsp.	= 18 gm.				
1 rd. tsp.	= 8 gm.				

CORN SYRUP.

1 oz. by volume = 33 gm. C.H. = 136 Cal.
45 cc. corn syrup + 55 cc. water = 50 gm. C.H. = 205 Cal.

COTTAGE CHEESE.

Cheese from 1 pint of skimmed milk contains 15 gm. protein and 60 calories. 1 pint makes 3 rounded tablespoonfuls.

DIAPROTEIN MUFFINS.

Recipe = 1 measure diaprotein flour (15 level tablespoonfuls)
1 egg
2 level tablespoonfuls of bacon fat
3 tablespoonfuls of water

This makes 6 to 8 muffins and equals 460 calories. 1 muffin = 65 calories if 7 muffins are made from the above recipe.

If no fat is used, the batch of muffins contains only 184 calories.

The best starch to add is rice jelly or zwieback, and in cases with poor starch tolerance one should be in no hurry to add it. If the child is doing well, it is best to let him go along for a considerable period, often several months, without any starch whatever. One of the first to recognize this important principle of an absolutely starch-free diet over a long period of time, or at any rate to write anything about it was, as far as I know, Dr. Philip Sylvester of Boston.*

Fat is added by working in a few ounces of whole milk instead of an equal amount of skimmed milk, but if much of this tends to come

*For his original paper, see the BOSTON MEDICAL AND SURGICAL JOURNAL, Aug. 26, 1920.

through in the stools, it must be again omitted.

Of the three vitamins A, B, and C, there is probably a sufficiency in this diet, with the possible exception of the fat-soluble A.* Despite this, the lack of this vitamin in such a diet seems to do no harm, and I know of one child who has been on such a diet for a year, and who has done remarkably well.

The fat-soluble vitamins can be furnished by a small amount of spinach purée if the child can handle it well, but as a general thing it is better to leave this out. Or the same thing can be supplied by the yolk of an egg.

Cod liver oil is, of course, a most potent source of this vitamin, and if one is afraid of vitamin deficiency, a half teaspoonful of cod liver oil three times a day will insure a sufficiency of fat-soluble A. An adequate supply of water-soluble B and C is probably furnished in the large amounts of milk taken.

The course of this disease, if the case is a severe one, is long, and even under the best conditions, progress is slow, and occasional relapses certain.

At the onset of a relapse the bowels should be cleaned out with a good-sized dose of castor oil, the child should be put to bed, and nothing given to eat but milk. These relapses are inevitable, and need not cause discouragement. A slight pharyngitis, the cutting of a tooth, getting overtired or overexcited may be enough to excite diarrhea, and to cause a considerable loss of weight in a short period of time.

To sum up: a disease, the essential nature of which is probably an infection of the contents of the small intestine with organisms which should not be there, this infection being usually caused in the first place by overfeeding with too much solid food at too early an age, or by an acute attack of diarrhea. The basis of treatment is a low starch and fat, high protein diet. Nothing whatever in the way of results can be accomplished without considerable painstaking study of each individual case.

SCHOOL CHILDREN AND SPINAL CURVES.

BY E. H. BRADFORD, M.D., BOSTON.

THAT our school girls carry themselves badly is an admitted and regrettable fact. It is doubtful if school gymnastics conducted as they must be, are adequate to give desirable results. Posture classes may induce strong-backed children to attempt to stand straight, but the weak-backed will continue to take faulty attitudes as long as their backs are weak. As faulty attitudes in children threaten to develop into fixed spinal curves in adults, every well-wisher of the race is prompted at every school exhibition or assembly

FIG. 1.—X-ray of fetal full term trunk showing the large amount of intervertebral cartilage.

of school children to demand more effective measures to correct the many flat-chested and round-shouldered individuals of the rising generation; yet the difficulty of the undertaking and the uselessness of inadequate efforts check the efforts of critics.

Curves of the spine in school children can be grouped into certain definite and easily distinguishable classes, requiring different measures for their correction, viz.—

1. Faulty habits of attitude in normal children.
2. Curved and sagging spines in children with weak spinal and trunk muscles.
3. Spinal columns with fixed faulty curves.
4. Twisted spinal columns.
5. Noticeably distorted figures.

Methods of treatment of curved spines in young, growing children, must differ from those employed in adults or even adolescents.

Deformities, *i. e.*, deviations in growing bone, tend to correct themselves if suitable conditions are furnished—nature favors growth to type.

Methods of treatment demanding rigid gymnastic exercises, class setting up drill, are with difficulty made effective with young children, whose muscular ambitions are not as fully developed as in later adolescence or young adult life.

In the days of rigid parental discipline, children who sat and stood badly were made to sit in straight-backed, shallow-seated chairs and lie on an ironing board and were roundly taken to task for slouchy attitudes. In these later days

*Skimmed milk contains a not inconsiderable quantity of the fat-soluble vitamins.

FIG. 2.—Fetal trunk opened in front with pins inserted in the vertebral bodies showing the amount of possible side flexibility without rotation of bodies.

the example of the past may be followed to the extent of recognizing the fact that the environment is of prime importance in securing good carriage.

The slouchy, flat-chested plebe becomes, after a few months at West Point, noticeable for his erect figure—the drafted civilian holds himself much better after a well drilled service than in civilian life—and it is to improvement in home as well as school habits of the young, growing child, that importance must be paid in the hope of avoiding crooked backs in young children.

If it is remembered how much each day of the time of the active life of a child is passed in chairs, the importance of proper seating cannot be overlooked. Recognizing the more erect carriage of children among the chairless races than among our better furnished people, the inference suggests itself that in many instances curving spines may be a chair back deformity, and that in the early preventable stages low stool sitting, reading and writing at tall desks, combined with resting a tired back on a hard, flat surface, may be corrective home habits.

The school furniture problem cannot be said to have been satisfactorily met and the fact that school desks and chairs must be, to a large extent standardized to meet school regulations and marketable conditions, presents a difficulty not easily overcome. Perhaps the only way at present that is practicable is to arrange for frequent interruptions in the seated time in school hours with frequent setting up exercises. At home, reclining boards, low stools and standing desks and active hard play present a possibility of improved home conditions. An arrangement of this sort might be adopted in small, unconventional schools, but the necessary change would be too radical for adoption in large, firmly organized schools.

When evident muscular weakness is present,

attention to the need of improvement of muscular strength is evident; class gymnastics, physical culture drills are all of importance, but the value of daily home exercises is not to be ignored. In fact, it may be regarded as of the utmost importance. In by far the greatest number of cases effective home exercises can be satisfactorily carried out. Where curved spines are under consideration, attention must necessarily be turned to strengthening those muscles used in holding the trunk normally, as well as to correcting curves. It is a noticeable fact that all people accustomed to carried weights upon their heads are erect. Head weight carrying if possible as a daily home exercise, naturally suggests itself as a useful daily exercise. This is easily arranged if sand bags of different sizes and weights are used at home at stated times both for children seated and walking. Other dumb bell or weight and pulley exercises can be made use of. In weak children exercises should be limited to suit the child's condition and should be accompanied by periods of regulated rest.

In weak-muscled children, it can be expected that as the muscular strength improves there will also be an improvement in carriage if no abnormal conditions in the spinal column have been developed. But where faulty habits in attitude have become firmly established, in many instances more than daily directions as to improved posture will be needed. A constant corrective device is needed to restrain from dropping the head or shoulders forward, dropping one shoulder.

These should not be so constantly used as to weaken muscles or establish reliance upon these artificial measures, but daily for a sufficient time to give the patient a sense of a better attitude. Such checking shoulder and neck straps should be simple and adjusted with little difficulty.

FIG. 3.—The same, showing the amount of rotation in downward pressure exerted on the spinal column.

A serviceable arrangement of this sort can be made with webbing. If a loop of inch wide webbing, sufficiently large to include the shoulder blade, be applied to each shoulder with the attached webbing long enough to be crossed behind and again across the abdomen and buckled around the hips, the shoulder blades can be drawn back whether the patient is sitting or standing. If to these loops a webbing strap is attached, passing around the front of the neck, the head and neck cannot be bent forward without discomfort and are held erect. Where the spinal column sags in the dorso-lumbar region and there is a marked hollow back, forward pressure is necessary on the sacrum and upper part of the spinal column with back pressure on the abdomen, while the shoulders are held back and the neck kept from bending forward.

This can be accomplished by a simple arrangement. Two strips of steel are fastened together in the shape of a cross, the short cross piece to extend across the shoulders at the level of the axillae. To the top of the upright arm of the cross can be fastened a band of ribbon or webbing which can be tied around the neck. To the end of the cross arms is attached webbing long enough to pass around the shoulders, crossed in the back, to be buckled in front to a square piece of leather or canvas placed over the abdomen. The bottom of this abdominal piece is secured by straps coming around the lower part of the trunk from the lower of the steel upright. The abdominal cloth can be kept from rising by garter supporters or by attached webbing straps passing around the thighs.

The patient can with this arrangement be kept

for a required portion of the day in a proper position.

A different arrangement is needed if the faulty position is one with dropping of one shoulder, the projection of a shoulder blade and of a hip.

A light stiff upright should be made, long enough to reach from the middle of the cervical region to the lower end of the spine and well on to the sacrum. At the level of the axilla of the dropping side or somewhat above this, a cross piece should be attached at the end of which should be secured a piece of webbing attached at its upper end to the cervical end of the steel upright. This webbing loop should be sufficiently long to allow the arm to pass through it. The lower end of the upright should be furnished with a webbing strip which will pass and be buckled around the thigh and groin on the side opposite that of the dropping shoulder. A strip of canvas three inches wide, should be attached to the upper end of the upright, pass around the projecting shoulder blade, around the trunk in front to be secured by straps and buckles to a similar canvas band passing around the hip on the side of the dropping shoulder and attached to the bottom of the upright.

If this appliance is properly adjusted, correcting pressure will be made on the projecting shoulder blade as required, the dropping shoulder raised and the side bend of the spinal column checked.

It is understood that these appliances are not to be worn constantly, but are to be used at such portions of the day when a slouching position is less easily corrected by muscular trunk action, when rest is not feasible and the patient is less vigorous in efforts for self correction.

The spinal column of the infant is flexible in many directions, even allowing twisting to a considerable degree. After weight-bearing has come to the growing child as a part of the function of the spine in the erect position, physiological curves develop in the need of the requisite balancing of the head while the body is moved and the pelvis shifts in its inclination. As attitudes become constant, these curves become to a degree fixed from adaptations in the shape of the ligaments, fasciae, cartilage and bones. If faulty attitudes are too constantly assumed, faulty curves from abnormal stiffness in portions of the spinal column and abnormal twists. In addition, the ribs, sternum and vertebrae connected with the spinal column, being subjected to abnormal muscular strain, may become abnormally shaped. This is especially true if for any reason the bony tissue is structurally below normal resistance, as in the condition. Abnormality of the bones may exist in rarer cases congenitally, or from early abnormalities in growth. When these exist, more thorough treatment is needed than can be furnished by muscular exercises, rest, or checking appliances.

Evidently the period when treatment can hope to be successful is during more rapid bone

growth. Feasible measures of corrective pressure can alter the shape and position of twisted ribs and to a degree the adherent vertebrae in the same way that the Flat Head Indians alter the shape of their skull, or the Chinese that of the bones of the foot.

The question of the extent and thoroughness with which correcting pressure can and should be applied in each individual case is one of judgment.

There is also the need in some instances of shortened ligament and fascia stretching, needing different methods and exercises from those required in muscular development. This fact is recognized in the training of circus performers and tumblers and it is an art in itself.

These methods may be classed as (1) intermittent, (2) constant pressure or pull, and (3) stretching exercises with the opposing muscles relaxed. The laws of growth are little understood, but there is undoubtedly a strong tendency of bone to grow to type.

This should be recognized by physicians in the management of young children. The underlying causes of deformity should be investigated and conditions favoring the normal secured.

There are two common causes favoring faulty attitude: (1) clothing which restricts the normal play of the trunk and shoulder muscles, and (2) chairs in which lounging or incorrect attitudes are habitually assumed. As in all households the chairs generally used are adult chairs and if habitually used by children for a considerable portion of the day, faulty positions of the spine are constantly assumed and may become habitual and are not to be overcome by a few exercises practised a few times a week.

Loose clothing with freedom from drag upon the shoulders is necessary as well as restriction of the time spent in unsuitable seating.

These methods may supplement or take the place of other measures already mentioned and should be used with due consideration of the physical needs and rights of the child for ordinary content and comfort.

According to the gravity of the curves in their threat of increasing deformity, correction should be by means of a constant or intermittent correcting force and should vary in degree of the pressing or pulling force.

In the most threatening cases, comparatively rare in young children, correcting force should be applied to the patient in a recumbent position. Correction of the curves of the spine are more easily effected when the superimposed weight is removed. Recumbency can be borne for a longer time without discomfort than suspension and is therefore to be preferred when corrective methods are undertaken.

If the trunk of a full term foetus be dissected, permitting an inspection of the movements of the spinal column under varying conditions, it will be seen that curvature with rotation can be produced by pressing the neck down toward

the pelvis, provided the spinal column as a whole is not permitted to curve backward. It will also be noticed that side bending is possible to a considerable extent without a twist in the column owing to the elasticity of the cartilaginous intervertebral tissues.

Under certain conditions of crowding of the vertebrae with side bending, characteristic scoliotic curves are developed. These can be corrected by suitably directed correcting pressure or a pull and removing downward pressure.

In fully developed adult scoliotic spines the amount of force needed for correction would be great. In younger cases the amount of force would vary according to the extent and degree of the curves but the principle of the correction would be the same.

This consists both of side pressure upon the points of greatest convexity of the curves and counter-pressure at the opposite parts of the curved trunk.

In flexible foetal spines, direct pull upon the column, forced backward or forward bending, will obliterate the twist, but this effect is not so easily produced in developed curves. In these, direct pull upon the head or pelvis may change twists in the cervical and low lumbar regions unless structural changes have become pronounced, but in the dorsal regions this result is not to be expected. For correction of rotation correcting pressure on the ribs must be employed to overcome the spinal rotation. Manifestly all downward pressure on the upper part of the column must be removed if rib correcting pressure is to be effective. A combination of side pressure and counterpressure with front and back pressure and to an extent, direct traction with countertraction or recumbency are all needed in complicated curves. If enough force could be applied in these directions and borne, every spinal curve could be corrected, and by the same reasoning it may be expected that the less resistant curves can be so corrected. All that is needed is the suitable application of correcting force.

Correction must, in growing bones, be applied constantly and persistently for a long period to check continuous perversity in growth. This necessitates home treatment daily applied by means of appliance of easy adjustment and simple construction.

If a child lies on a board, either flat upon the floor or for the child's greater convenience, on a board raised at one end, and a short board pressed upon the front of the thorax, pressure to any desired extent can be made upon the distortedly rotated ribs by connecting the two boards at the sides by straps. The areas of pressure can be farther regulated by thick, firm pads placed on the areas needing pressure. A head-pulling sling and side-pulling straps attached to weights can be added to act upon the curves and to reduce downward pressure. The plane and angle of the pelvis can be changed by

flexing or straightening the thighs and by exerting a pull on one or the other of the legs if the limbs are kept straight, or if the thighs are flexed by attaching to the reclining board a seat on which the buttocks rest which can be made by suitable adjustment to exert more pressure on one buttock than the other.

The degree to which the correcting forces are to be exerted is a question to be decided in each instance. This recumbent correcting treatment can be made less tedious if the resting board be inclined so as to permit reading.

When intermittent correction seems inadequate and constant correcting pressure is needed and when the patient is about and also when in bed, correction can be exerted by means of a bivalve corset of celluloid or stiffened leather made from a properly applied plaster corset reaching from the neck to the pelvis and exercising correction on the spine as far up and as low down as possible.

Care and skill are required in the making and adjustment of this corset that there may be a minimum of discomfort and disfigurement when it is worn. This corset being removable and its pressure adjustable, its use is compatible with muscular exercises and free activity, according to the needs of the case.

As treatment to be effective must be protracted, the means employed should be as simple as possible suited for the capabilities of domestic nursing.

They need, however, careful and observant medical supervision at stated times to direct changes in methods used to note accurately improvement or the reverse.

If the spinal column is abnormally stiffened in its curves in any part of the spine and not flexible to any muscular contraction, it cannot be considered as rational treatment to attempt to strengthen the muscular group in question until the respective portion of the spine is restored to its normal flexibility. This, if due to ligamentous shortening, is to be accomplished by ligament stretching and not muscular exercises. Muscular exercises of the trunk or thigh muscles may be beneficial at all times, but should be carefully directed that they may not develop the muscles already sufficiently strong without benefiting those weakened owing to an abnormally stiffened spine. A safe rule in these cases is that all muscular exercises should be taken with the spinal column in as nearly a corrected position as possible.

In watching chronic cases of the nature of spinal curves when changes are necessarily gradual, it is necessary that the surgeon directing treatment should have more accurate data of the state of the curved spine than that furnished by his own recollections of the observed condition several months before.

Variations from the normal side flexibility curves can be used to indicate the portion of the spine needing treatment for overcoming local-

ized abnormal stiffness and the amount of success following measures used in treatment, giving greater precision to the surgeon's method and greater definiteness to his judgment.

It would be, if practicable, desirable to publish in a statistical form, or by more definite before and after treatment presentation of cases, the results of many years' experience in the treatment of spinal curves by different methods, but by the nature of the case the long chronicity of the affection, the unknown factor of natural improvement, and the many circumstances which check the benefit of treatment, statistics possible in the results in operative surgery are less trustworthy if dealing with spinal curves.

To any one who has studied the subject and witnessed the great increase in the knowledge of the subject in the last forty years it is evident that the surgical world has passed through the period of clumsy and futile treatment of little understood distortions to a stage where definite improvement can be expected to follow persistent rational corrective measures. The advantage of effective and not too irksome preventive measures in the curvatures of growing children is evident. When many treated cases have been watched from childhood to strong manhood or to motherhood there can be no doubt as to the advantages of proper corrective measures over expectant or spasmodic or ineffective methods.

Success can be expected in preventing the development of fixed curves in growing children threatened by faulty habitual attitudes, the checking of progress, and in some cases correction of already established curves.

With proper attention on the part of the parents, school authorities and physicians, it may be expected that future generations will have better carriage and straighter backs than are at present seen among school children.

SPINAL FLEXIBILITY.

BY E. H. BRADFORD, M.D., BOSTON.

If the spinal column from a dissecting room cadaver or if the vertebrae of an adult skeleton are articulated in such a manner as to simulate the natural condition, certain curvatures and limitation in the movement of the whole spinal column are to be observed. This condition of fixed curves or of restricted movement is not found to the same degree in the spinal column of a full term foetus owing in part to the greater cartilaginous structure in the bodies of the immature spine and the greater elasticity of the articular facets and ligaments. The foetal or new born infant spine may be said to have no curves and to be movable with considerable flexibility in directions which in adult spines meet resistance.

FIG. 1.—Contour tracing and tracing of lateral flexibility of spinal line in a normal child showing greater lateral flexibility to the left side.

FIG. 2.—Contour tracing and side flexibility of the spinal line in an infantile paralytic showing change in lateral flexibility.

TRACING; SIDE VIEW

TRACING; LATERAL FLEXIBILITY.

In the study of pathological curves a knowledge of flexible spines is needed.

If a full term foetal torso is examined it will be seen that the osseous structure of the verte-

brae of the spinal column is considerably less than in a developed spine, and the same will be found to be true in a growing child in extent corresponding to the osseous development. There will be a corresponding greater amount of spinal flexibility in the column in proportion to the amount of cartilaginous structure in the vertebrae. It is of interest and importance to determine the limit of normal side flexibility in the most flexible spine as well as in each individual case presented for examination.

If the thorax of the foetal torso is opened and the lungs and heart removed and pins inserted in the vertebral bodies, the amount of possible bending of the column without causing vertebral rotation, the most distorting strain on the column can be noted and also whether pressure on the ribs in the back will cause a twist of the column.

It will be seen that in a flexible spine pressure on the ribs on one side in the back will twist the spine at the corresponding portion of the column. It is also to be observed that in a straight spine twisting the column at either end

Lateral Curvature Brace and Spinal Straps (Front).

Lateral Curvature Brace and Spinal Straps (Back)

causes rotation at the end twisted, but not in the middle.

Furthermore, if the spine is arched backward pressure on the top of the column down toward the pelvic end does not cause vertebral rotation, while this pressure does if the spine is bent forward. Side bending does not cause vertebral rotation if the column is bent backward.

The significance of these facts in determining the causation of rotation distortions in the trunk is evident. A spinal column kept straight or bent backward does not twist from superimposed weight, while if bent forward there is danger if the column is overloaded of a twisting strain which, in case of structure inability to resist, will cause distortion if the strain is continuous, especially in the less flexible portions of the column less able to relieve themselves by backward bending, of constant distorting strain.

In cases of curvatures of children under observation it is desirable that the flexibility of the different parts of the column be examined and noted, as well as any abnormality in the spinal curves. Simple means of determining both the curves and the spinal flexibility are desirable,

Self-Correcting Stretching Exercise for Stiffened Curves.

Reclining Board with Front Pressing Board for Twisted Curves.

FIG. A, B, C, faulty sitting and standing attitudes; D, trunk contour in floor sitting; E, check-rim brace in round shoulders; F, lateral curve; G, light steel brace; H, spiral webbing and strap applied to give correcting pressure.

and can be furnished with sufficient accuracy. Various devices have been employed for tracing variations in the spinal lines, *i.e.*, the marked skin line over the projecting vertebral spines, as well as of the contours of the trunk. Simple arrangements for the purpose have evident advantages, and can be made by attaching a tracing pencil at one end of a short light rod in such a way that the pencil maintains the right angle position to the tracing paper and that the rod can be held at a level while the pencil is passed over the line to be traced, *i.e.*, the line of

the spines or any section or contour of the trunk. The pencil-holding end of the rod will mark a traced line on a paper pinned on a board at the side of the sitting, standing or stooping patient.

In tracing the sides of the trunk an accurate record can be made if the patient stands back against the board and the tracing pencil (placed in a holder to keep it at right angles to the tracing plane) is passed along the patient's sides.

There are several other methods of tracing back curves: the simpler one described appears to be the most generally serviceable. When the flexibility of the spinal column is to be noted the patient is bent to one side and the other alternately and steadily in the required position. Although antero-posterior tracings can be made and are important, yet in studying beginning or threatening twists the side flexibility seems of the most value as a premonition of possible rotation, through faulty weight-bearing. There will be found much variation not only in the lack of symmetry in the side motions in an individual, but also in the location of the centers of greater side flexibility in different individuals. These variations may in flexibility tracings be regarded as the result of variation in habitual attitude or variation in growth in children.

In many instances they may be within what may be called normal physiological limits. In others they may approach the pathological.

A study of the flexibility of the infantile spinal column compared with the localized restricted mobility in definite parts of the column in the adult is an aid to the investigation of the problem of the causation of spinal curves. To this should be added some knowledge of the changes in the skeleton as the animal develops from the quadruped to the biped. The spinal column in the quadruped is supported on four legs and is little exposed to the twisting side strains of ambidextrous, erect, moving man. The animal quadruped is also freed from the strain upon the column of the superimposed weight of the head and upper trunk. In the bipedal bird the symmetrical action of the wings prevents unequal side strains on the column and those of superimposed weight are diminished by the oblique inclination of the spine and the small size of the head. The quadrupeds are not erect and their arboreal activity hanging by the arms protect the column from distortion from superimposed weight.

In man as soon as he assumes the erect attitude, emerging from the infantile stage of ereping activity, the spinal column is exposed to strains not occurring in other animals, and for which the normal spinal column must become adapted in its skeletal form and its muscular and ligamentous strength and elasticity.

The sacral end of the spinal column is firmly attached to the pelvis and but little mobility exists at the articulation of the last vertebra and the top of the sacrum; forward and back or

side movements in the column take place at a short distance above in the lower lumbar region. In the quadruped the pelvis is roughly at an obtuse angle with the line of the spinal column. In the floor seated infant the pelvis would be at right angle with the spinal column, provided the spinal column was supplied with sufficient muscular strength to sustain the head and trunk weight without bending under the load. In the standing position, however, the pelvis inclines downward at the front, and this inclination pulls with it the last lumbar vertebra, giving a lumbar forward arching and a resulting compensatory curve above. The extent of these curves depends upon the muscular strength and the tensile power of the ligaments holding the vertebrae and the column to the pelvis.

The surgeon in examining and in treating spinal curves will find tracings as described of much assistance in determining the existing condition in a given case, the prognosis, and in the needed method of treatment.

THE ELECTROCARDIOGRAPHIC SIGNS OF CORONARY THROMBOSIS AND ANEURYSM OF THE LEFT VENTRICLE OF THE HEART.*

BY MORRIS H. KAHN, M.A., M.D., NEW YORK CITY.

IN order to understand the changes that take place in the electrocardiographic records of cases of coronary thrombosis, it is necessary, first, to set definite limitations to the normal electrocardiographic picture.

The electrocardiogram traces the course of the conduction current through the heart, beginning at the sinus node in the right auricle through the auricular wall, the a-v node, the junctional tissues, the bundle of His and its branches, and via this structure throughout the ventricular wall. This gives normally a characteristic picture.

First, comes an auricular wave, designated as "P," of an average duration of 0.12 of a second. Then, an iso-electric period follows; the conduction current reaches the ventricular muscle and gives rise to the Q R S wave, lasting normally up to 0.1 of a second. After another iso-electric interval, the T wave, which is considered to indicate the deactivation of the ventricle, takes place.

This normal picture may be influenced not alone by organic changes in the heart, but by functional changes as well. These may effect the sinus node, producing fibrillation of the auricle; the auricular wall producing auricular extrasystoles; the a-v node producing abnormal rhythm; the bundle of His producing heart block; or the ventricular muscle producing ventricular extrasystoles. These changes may also be due in part to organic causes.

* From the Department of Cardiovascular Diseases, Beth Israel Hospital, New York City.

A lesion at any point in the ventricular heart structure will affect either its irritability, conductivity, contractility, or rhythmicity. Affecting irritability, extrasystoles would result from the points of hyperirritability; affecting contractility, variations in voltage and alternation in the force of contraction might occur; and disturbed rhythmicity would give irregularity of the heart.

The important point in the differentiation is to ascertain whether the basis for the change is organic. Minute organic changes, unless they affect the conduction mechanism of the heart, we are not yet able to discover with certainty. When the changes are such as would result from coronary thrombosis, they are more or less distinctive and amenable to careful analysis of the electrocardiogram.

For a better understanding of these changes, it is desirable to be acquainted with the main vessels of supply to the heart itself.

The heart is supplied by the right and left coronary arteries arising from the sinuses of Valsalva just above the semilunar valves. The left coronary artery is the more important, being the more likely to thrombose or occlusion. It courses in the left ventricular groove to supply the anterior wall of the left ventricle, the anterior papillary muscle and the left half of the thickness of the interventricular septum. Its circumflex branch turns posteriorly in the auriculo-ventricular groove supplying the posterior wall of the left auricle and of the left ventricle, the posterior papillary muscle and part of the septum. The right coronary artery runs along the right or posterior interventricular groove and supplies the right ventricle over its main extent. Its circumflex branch continues forward around the right side of the heart, supplying the right auricle.

From a practical clinical standpoint, we may consider the coronary endings as terminal arterioles. Though the capillaries may anastomose slightly when a coronary branch is occluded, the anastomoses are not sufficient to maintain such adequate nutrition of the heart as to prevent the development of symptoms.

The changes that can occur when the coronary vessels are occluded are those of anæmic infarction and necrosis. At first, such a lesion is distinctly inflammatory and, therefore, a source of irritation to the heart muscle, producing hyperirritability of the heart at that point. This would result in premature beats or a series of premature beats producing paroxysmal tachycardia. As a matter of fact, coronary thrombosis is very often followed by an attack of paroxysmal tachycardia, as will be illustrated by one of our cases to be reported.

The lesion continues to progress with destructive changes, increasing the difficulty for conduction.

When these changes involve the special fibers of conduction, a certain degree of blockage to the conduction current takes place in the ven-

tricular muscle. In the electrocardiogram, this is manifested as an increase in the Q R S period, which may extend to 0.2 of a second; *i.e.*, the conduction current, not finding a clear course through the branches of the bundle of His, must traverse the ventricular muscle and its connective tissue, and the latter offer much more resistance than the specialized fibers. This increase in the Q R S period becomes a significant feature of the electrocardiogram in coronary thrombosis.

The degenerative changes continue. If the coronary thrombosis involves the apex of the heart, as it frequently does, connective tissue may entirely replace the muscle with thinning and dilatation of the ventricular wall. This produces a not very uncommon lesion, an aneurysm of the wall of the left ventricle. Aneurysm of the left ventricle, therefore, being commonest at the apex of the heart, will give a more or less distinctive picture in the electrocardiogram.

Low voltage with preponderance of the left ventricle and slight widening of the Q R S wave, and these features progressing with the progress of the lesion, are the findings in this condition.

There is not that extensive notching of the Q R S wave or the high voltage as takes place in lesions involving the septum itself.

Extrasystoles may occur in this condition, depending upon the progress of the lesion in the boundary zone of the aneurysm where it joins the normal tissue.

The "T" wave also shows quite characteristic changes with thrombosis of the coronary artery. Experimentally, ligation of the descending branch of the left coronary artery produces characteristic alteration in the "T" wave. Immediately following the ligation, the "T" wave becomes more prominent, varying in height with the size of the ligated branch. It then becomes sharply negative and, after several days, it gradually becomes positive again, first in lead III and last in lead I. After a number of weeks, it again becomes iso-electric or negative and remains so until death. These changes are undoubtedly associated with the progress of pathologic changes in the infarcted area.

This change of the "T" wave from a strongly positive peak to a markedly negative one, and then a slow return to the positive or iso-electric form is so characteristic experimentally that similar changes in the wave in man may reasonably be supposed to be due to similar lesions in the left coronary artery.

It is, therefore, important in cases of suspected coronary thrombosis not to confine oneself to a diagnosis from a single record, but to take records repeatedly. What may be found more important than the analysis of a single record is the variation in the electrocardiographic picture with the progress of the lesion.

Ventricular extrasystoles and paroxysmal tachycardia early in the cases, with blocking of the conduction current in the ventricular muscle and progressive changes in the "T" wave are

the possible pictures in coronary thrombosis. These can be illustrated, in brief, by the following three cases and their electrocardiograms.

REPORT OF CASES.

CASE 1.—S. Z., Russian, aged 58 years, complained of dyspnoea on exertion of five to six months' duration and cough and expectoration. He had severe cardiac pain and an attack of paroxysmal tachycardia, for which he was admitted to the hospital.

The physical examination showed slight congestion of the pulmonary bases and marked dilatation of the heart to the anterior axillary line. Its action was extremely rapid and regular. The respirations were labored, 36-40 per minute, and the temperature was slightly elevated.

Laboratory Observations.—The urine showed a considerable amount of albumin. The Wassermann test was negative. The blood showed 10,000 leukocytes and 76% polymorphs. Pericardial fluid aspirated contained 60% polymorphs and 40% mononuclears.

Polygraphic Studies.—The jugular wave was of the venous type, as is usual in paroxysmal tachycardia. The radial showed distinct pulsus alternans.

Electrocardiographic studies were made repeatedly and showed left ventricular preponderance and paroxysmal tachycardia of ventricular origin. The rate was 168. Moderate ocular pressure did not affect the heart mechanism. (Fig. 1.) Roentgen ray studies revealed a marked

FIG. 1. Paroxysmal tachycardia of ventricular origin due to coronary thrombosis. (Case 1.)

enlargement of the cardiac shadow, especially the left ventricle.

CASE 2.—Z. M., Austrian, aged 51 years, complained of shortness of breath and was seized with pain over the upper portion of the abdomen, which radiated to the chest and which was accompanied by marked dyspnoea.

Physical examination showed the heart enlarged to the left. The apex was in the sixth space. The sounds were weak and of poor

muscular quality. There was evidence of marked mitral and tricuspid regurgitation. There was prominent pulsation of the veins of the neck, and the liver was also felt pulsating just above the level of the umbilicus. Respirations were labored and the pulse was weak. Effusion into the right chest showed signs of right failure.

FIG. 2.—Polygraphic tracings of the radial with pulsating liver (above) and radial curve (below). The hepatogram shows the ventricular form of liver pulse (tricuspid regurgitation). The phlebogram presents the normal sequence of waves, a, c, v, with perhaps increase of the a-c interval. The fourth cycle in the jugular tracing is a nodal extrasystole with superposition of the auricular and ventricular waves; this is followed by a complete compensatory pause.

FIG. 3. Case 2. The voltage is a little less in this record than before. The T wave in lead III is upright in this figure, but it became negative later. A nodal premature beat is shown in lead III.

FIG. 4.—Descending branch of the left coronary artery in Case 2, showing atherosclerotic deposits and thickening of the wall.

FIG. 5.—Almost complete obliteration of the lumen of the descending branch of the left coronary artery in Case 2, due to thrombosis.

The patient died with sudden cardiac exhaustion four months after the onset of the symptoms. Polygraphic studies showed tricuspid regurgitation and pulsating liver, and also occasional ventricular premature beats. (Fig. 2.) Electrocardiographic studies repeatedly showed left

Laboratory Observations.—The Wassermann reaction was negative. The blood showed a slight secondary anemia and a slight leucocytosis of all three leads, which became still lower before between 9,200 and 13,600 cells per cu.mm. the patient died. The Q R S wave was notched

and widened in all three leads to 0.12 of a second; this was most evident in lead II. The "T" wave was inverted in lead I throughout and continued from the "S" phase without any iso-electric interval. Toward the end, it became less distinct and almost iso-electric in leads II and III. There were occasional bundle and nodal extrasystoles. (Fig. 3.) Autopsy findings revealed a much enlarged heart, with an old patch of pericarditis. The wall of the left ventricle was very thin and gradually tapered down to the apex, where the wall was only about 1 mm. thick. Here the muscular tissue was almost completely destroyed. Large plaques of firm connective tissue were visible throughout the wall, and especially on the septum. The mitral and tricuspid valves admitted three fingers easily. The coronaries showed partial obstruction, with calcareous deposits on the wall. (Figs. 4 and 5.)

CASE 3.—R. N., woman, 46 years of age, who complained of dyspnoea and sticking pains in the chest, especially on lower sternum. She appeared extremely weak; her face showed a peculiar sallow leaden pallor and an expression of anxiety and suffering such as is commonly seen in angina pectoris.

The physical examination showed neither enlargement of the heart nor murmurs at first, but the sounds were feeble. The respirations were labored, and bilateral pleural effusion developed.

Sudden death occurred five months after the first symptoms.

Laboratory Observations.—The Wassermann

FIG. 6. Case 3.—The Q R S wave here shows increased notching and thickening in lead II, with increased widening to 0.12 of a second. The T wave is less prominent than before, is almost iso-electric in lead I, but shows the same peculiar S-T transition in all three leads. This record shows greater voltage and greater predominance of the left ventricle than before.

test was negative. The blood showed a moderate degree of secondary anemia and a slight leucocytosis; at first, 10,000 leucocytes per cu. mm., and towards the end, 16,800 to 20,800 per cu. mm.

Electrocardiographic studies showed very low voltage and preponderance of the left ventricle, which increased with the course of the illness. The Q R S wave was slightly notched, thickened and widened, and became more distinct with the progress of the lesion. The "T" wave was at first inverted in lead I and fell directly from the descending or cataerotic arm of "R" before the latter had reached the iso-electric level. Later it became less prominent and almost iso-electric

FIG. 5. Descending branch of left coronary artery in Case 2 near its origin, showing a mural thrombus with beginning organization.

FIG. 8.—Section of descending branch of left coronary artery in Case 3 in its course, showing the extension of the thrombus murally into the branches of the vessel (one to the right and one to the left).

in lead I. Throughout, the electrocardiograms gave evidence of rapidly progressing myodegenerative changes in the left ventricle. (Fig. 6.)

Autopsy findings revealed an enormous heart and shaggy pericardium as a result of old tough lesions. The right ventricle occupied a comparatively small area, but the left ventricle was enormously dilated. The apex wall had been thinned to the thickness of blotting paper. The endocardium had been undermined by dissecting thrombus and the apical muscle was completely transformed into connective tissue. A huge, ovoid, laminated, hard white clot firmly attached to the septum almost completely occupied the ventricular cavity. The aortic ring showed marked atheroma.

The coronary artery admitted a medium-sized probe for a distance of $2\frac{1}{2}$ cm. Beyond

that, the anterior or descending branch of the left coronary was completely occluded. (Figs. 7 and 8.)

COMMENT.

These cases, corroborated by autopsy findings, serve as examples of the effects of sudden and progressive occlusion or thrombosis of the coronary artery. In the first case the infarction was acute and the myocarditis terminal. In the last two cases, the myocarditis was a rapid, progressive, degenerative condition with the formation of aneurysm and autopsy findings of great interest.

Two of these cases are included elsewhere in a clinical discussion of the subject of "Aneurysm of the Left Ventricle."¹ They are here given in their special relation to the electrocardiographic signs of coronary thrombosis.

THE ROENTGEN RAY TREATMENT OF ACNE VULGARIS.*

BY RUDOLPH JACOBY, M.D., BOSTON.

A SURVEY of the most recent literature shows that in the opinion of most dermatologists and roentgenologists the Roentgen rays constitute practically a specific treatment for Acne Vulgaris.

There are a number of clinical varieties of Acne Vulgaris, and a knowledge of the effect of

roentgenization of the various types of the disease is necessary in order properly to select patients for this treatment. It is of equal importance that modern apparatus and technique be used, and that a thorough knowledge of the biochemical and biological effects of the Roentgen rays be possessed by the operator.

All types of Acne Vulgaris have certain features in common. The disease is most commonly encountered at or about the age of puberty. It is very common in adults. The site of predilec-

*Read before the Althean Club, Boston, December 17, 1921.

tion is the face, although it frequently attacks the back, the back and sides of the neck, the chest, shoulders, and arms. The disease is an inflammatory condition occurring in and around the sebaceous glands, and is characterized by comedones, papules, pustules, and nodules.

The predisposing causes of acne are varied and many, and, as Martin aptly states, it may be produced by almost anything from indigestion to a state of exalted self-consciousness. However, the actual cause is the *Acne Bacillus* which is invariably present in all acne lesions. This bacillus was first described and named by Unna in 1893.

Most investigators believe that the earlier lesion, that is, the small papule, results from the infiltration of plasma cells, giant cells, mast cells, and fusiform cells about the outlets of the sebaceous glands. As the infiltration continues and the entire gland and later the hair follicles are surrounded by the infiltrating cells, a large papule and finally a tubercle are formed. At times several glands and follicles may be involved in one lesion.

When suppuration sets in, leucocytes appear and the glandular structure is destroyed. In some cases the destructive process also involves the hair follicles, and small dermic abscesses may be formed. Semon states that a periglandular fibrosis occurs that is often exceedingly dense. This fibrosis, he feels, protects the bacteria lying within the glands from the action of vaccines.

Of the more common varieties of acne, namely, comedo, acne papulosa, acne pustulosa, acne erythematosa, and acne indurata, only the erythematous type does not well tolerate roentgenization.

It is neither necessary nor advisable to treat every case of acne with the Roentgen rays. The proper application of various internal and external remedies, together with hygiene, will suffice to cure a great many of the cases. However, these cases may be regarded as too trivial to make Roentgen therapy necessary. In the more severe cases it is difficult to obtain the complete cooperation of the patient in carrying out the campaign of home treatment. Details are neglected, and if improvement does not occur rapidly the patient is apt to become discouraged and frequently makes the rounds consulting other physicians in hopes that an easy and quick method of cure may be found.

The Roentgen rays, if properly applied and combined with other means of combating the disease, offer a treatment that is associated with safety and prompt and permanent cure. Roentgen therapy obviates the necessity of using local remedies that are temporarily disfiguring and troublesome, and it usually effects a cure in three to four months, providing that the patient receives proper advice and treatment. The percentage of cures reported is very close to ninety per cent., and the percentage of relapses, which are very amenable to treatment, are small, probably not greater than five or six per cent.

In 1896 Ullman reported the first case of acne vulgaris cured by the Roentgen ray. A few more cases were reported between this time and 1900, immediately following which numerous reports began to appear in the literature. Many of these references are given by Pusey and Caldwell.

In these early days the dosage varied amongst the investigators from large erythema doses to the small divided dose. The results were very variable, and many accidents, serious complications and sequelae followed. This was in the days of the cranky gas tubes in which accurate control of constant quality and quantity of the x-ray was impossible.

Within the past six years, due to the pioneer work of MacKee and others, the development of the Coolidge tube and standardized apparatus, a technique has been developed which in competent hands is safe and effective.

Satenstein and Remer in their work on dosage from the pathologic point of view have found that normal tissue elements are more resistant than the pathologic. They state that the resistance varies according to the age of the person, the part of the body, and the type of tissue of which they are a part. The intensity and duration of the response of the cells to Roentgen rays are in proportion to the degree of their resistance, that is, the response is most intense and of longest duration in the cells of least resistance. After Roentgen ray exposure, the resistance of all cells is influenced, and their activity is proportionally affected. The more resistant cells recover in less time than those of less resistance. If the interval between the exposures is sufficiently long, all the cells will recover. After the second exposure, the activity of the cells that have not fully recovered is more readily affected, as their resistance has already been influenced. With each successive exposure the resistance is more and more influenced and the activity is proportionally less and less maintained. When the cumulative effects at the point of saturation are reached, the cells become non-resistant and inactive. (The rapidity with which the point of saturation is reached depends on the character of the cells and the intensity of the exposures). At this stage involution sets in, that is, the non-resistant and inactive tissue elements are unable to withstand the action of the local tissues assisted by the body's protective forces, and are absorbed. If involution is within bounds, normal absorption results, otherwise atrophy or ulceration may occur.

As the intensity and the duration of the response to the Roentgen ray are in proportion to the resistance, the pathologic cells will not have recovered to the same degree in the same time.

Chronic inflammatory tissues are characterized by the presence of fibroblasts (connective tissue cells). They are more resistant and less readily influenced than the lymphocytes (round cells) which characterize acute and subacute inflammatory tissue. Therefore, the best results to be

obtained in chronic inflammatory tissues is by the use of fractional doses.

As it is never the agent, but the response of the living cells to the agent that is responsible for therapeutic results, the least amount of rays necessary to produce these results in any given tissue should be employed.

In treating acne vulgaris by Roentgen ray, a standardized apparatus consisting of an interrupterless transformer, rheostat control, standard Coolidge tube, Coolidge transformer and control, and a milli-ammeter must be used. The dosage is measured in skin units. The experiments of Remer and Willoughby show that a three-inch spark gap and three milliamperes of current given for four minutes at an eight inch distance delivered the amount of ray corresponding to four Holzknecht units; namely, four numbers on the Holzknecht radiometer.*

Four Holzknecht units, that is, four numbers on the Holzknecht scale, correspond to one skin unit, which is a sub-erythema or epilating dose. On the basis of their experimentation they devised a formula which has become known as the national formula for cutaneous therapy. The strength of the ray varies inversely as the square of the distance.

The present accepted technique in the treatment of acne is to give fractional doses of one-quarter skin unit (one Holzknecht unit) weekly for from ten to sixteen treatments. This number should be used even though all symptoms have disappeared following only a few treatments. It is very seldom that patients cannot tolerate this dose.

In some young females with fair, finely textured, highly colored skins, and in some cases of acne erythematosus also, low toleration has been found. In these cases a smaller dose is given, that is, one-eighth skin unit.

The question of idiosyncrasy is often brought up, but most authors deny this possibility and explain poor results by errors in dosage and imperfections in the methods used.

One quarter skin unit is given once a week to each side of the face. In doing this there is ordinarily enough overlapping to cover the front of the face, but if there are many lesions on the chin and forehead, it may be necessary to give an extra one-eighth skin unit to these areas. The hair, eyes, and eyebrows are to be protected by lead foil. In treating the back and chest, slightly larger doses may be given. By giving this amount at these intervals an erythema dose is never administered since the effect of the first treatment has gone entirely before the next one is given. If there is the slightest sign of erythema, the dose is not repeated until its disappearance indicates normal tissue recovery. The presence of erythema is judged by noting the border between the area treated and the shielded skin about the eyes. This must be noted in clear natural daylight.

*This is the indicator of a color test dependent upon the coloration of disks of platino-cyanide of barium by the x-rays.

It is unnecessary to use any local treatment, and patients must be cautioned about the use of any soaps or salves containing drugs such as chrysarobin, iodine, salicylic acid, tar, mercury, resorcin, scarlet red, salicylic hydrate, or sulphur for a considerable time before or after treatment because of the fact that these substances render the skin more susceptible to irritation and burn.

Autogenous vaccines are frequently used by some as a supporting treatment, but most authors feel that this procedure promises nothing.

As in any disease it is also necessary to control any underlying factors such as focal infection, etc., when possible to do so. Regulation of diet and relief of constipation are frequently necessary, and scalp conditions which are usually associated with acne must be treated.

All potent therapeutic measures are dangerous in unskilled hands, and the x-ray is no exception. However, with caution, good judgment, and modern apparatus and technique, the Roentgen ray treatment of acne vulgaris is not only the best method, but a perfectly safe one.

None the less, we hear a great deal about complications and sequelae. Telangiectasis and atrophy can occur only from over-dosage. This is so rare that it scarcely needs mention, but the following complications warrant a few words:

Dryness of skin:—The skin may become dryer than normal during treatment so that it is easily irritated by wearing apparel, etc., or too frequent washing. This condition is readily controlled by a simple ointment and is only transitory.

Freckles:—Some brunettes show various degrees of pigmentation, but this condition is evanescent, although for the time being it is annoying to the patient.

Pitting:—It is generally conceded that this is a psychological matter; that the pits are due to the disease itself and as the disease clears up, the pits simply become more conspicuous.

Superfluous hair:—In so far as superfluous hair and acne are both due to an abnormal condition of the pilosebaceous gland system, we frequently observe the two conditions together. It will also be noted that usually the hair complained of is most marked under the chin where practically no treatment is received.

Conclusion:—The use of the Roentgen ray in acne vulgaris is the best treatment we possess, and in the hands of an operator who follows modern measured technique, and who is careful to keep his apparatus in good working order, is perfectly safe.

Book Reviews.

The Heart as a Power-Chamber. By HARRINGTON SAINSBURY. Oxford Medical Publications, 1922. 248 pp.

This book takes up the subject of the heart and circulation from a somewhat novel point of view. The particular emphasis is on the mechanical side of the circulation with a discussion of hydraulic principles. Although this idea is a laudable one, there would seem to be no excuse for the publication of such a book as this proves to be. A brief article of a few paragraphs or of a few pages at the most would have been more than sufficient to cover the ground.

The book is easy to read for there is little technical detail mentioned in it, but it grows very tiresome as a result of repetition and wordiness. The English at times is very quaint and reminds one of medical works written centuries ago, but the very quaintness of style does not excuse the vagueness and inaccuracy of the book.

There seems to be an attempt in this book to express a reaction against some of the more modern work on the circulation. This is, however, simply an attempt, because no proof is given that this modern work on the heart is not of far greater importance than most that has preceded and for which the writer of this work seems to be the champion. For example, there is a constant harping on the back pressure theory, which had been for years one of the bugbears in medicine but which now, in the light of more recent work, we thought had been dissipated. Once in a while there is a useful observation such as that concerning the relationship of the velocity of the blood stream to the cross section area of the circulation on page 90, and the diagram on page 93 illustrating the blood circuit. In the main, however, the information to be derived from the book is very little and may be typically represented by the following two paragraphs quoted, the first from the preface and the second from the chapter on Treatment, which chapter, by the way, barely mentions digitalis and gives no direction for its proper use, and praises the administration of such drugs as strychnine, camphor and eserine as cardiovascular stimulants.

"And what are we to say of design, that other salient feature which the study of struc-

ture brings out? This at least, that the more we look at it and into it, the more does its supreme art appear, and nowhere more so than when we search the chambers of the heart. Well may Borelli call this organ 'hanc mirabilem structuram,' and well may William Blake, the mystic, innocent of science and all its ways, exclaim in that strange poem, 'The Tiger':

'And what shoulder, and what art
Could twist the sinews of that heart?'

Whence came the inspiration which thus spoke,
and whence the insight?"

"The first aphorism meets us at the very portals of the temple of Aesculapius, and like a solemn introit conducts its votaries across the threshold. It tells of the brevity of Life, and of the interminable pursuit of Art (life's task); it tells with unerring directness of the urgency of the Moment, that is, of the swift passing of Opportunity's escaping forelock. The next pronouncement cries halt, despite all the need for haste which the crescendo argument has developed up to this point; for now it bids us pause and consider that Experiment is hazardous, in that, apart from the peril of active intervention, we may perchance thwart the healing powers of Nature; and, again, that Judgment is difficult, not to say fallible. The problem thus confronted, there follows as a corollary the immediate practical deduction which must be acted upon without delay, yet without undue haste, having first given the mind time to visualize the problem in its entirety and to consider the vantage point of Opportunity, in time and place: the second half of the aphorism embodies this conclusion."

"Explicit." ???

A History of the National Tuberculosis Association. By S. ADOLPHUS KNOPF, M.D. National Tuberculosis Association, New York.

In this volume Dr. Knopf has brought under one pair of covers a remarkably large and accurate amount of information. The story of the tuberculosis campaign in this country has been a striking one of tremendous progress, not without its romantic and even its tragic sides. Dr. Knopf has undertaken a great task, which he has accomplished well in the present volume. The book is a large one of nearly 500 pages, but attractively gotten up, well printed and arranged.

The first part describes the early history and development of the National Tuberculosis Association, devoting especial attention to its organization, early problems, the tuberculosis Christmas Seal campaign and the Framingham Demonstration.

In the second part is a brief summary of what took place at the seventeen annual meetings of the National Tuberculosis Association which have thus far been held.

The third part consists of 49 biographies, with photographs, of the officers of the Association.

In addition there are three appendices:—

I—describing anti-tuberculosis work during and after the World War;

II—a list of publications of the National Tuberculosis Association;

III—which the reviewer is frank in admitting that it might with better taste have been omitted—a list of Dr. Knopf's writings. Exactly why he chose to include these in a history of the National Tuberculosis Association, with which it is not fundamentally concerned, is not easy to see.

The book, however, is a valuable contribution in that it presents a permanent record of one of the great movements toward the betterment of mankind.

Smell, Taste, and Allied Senses in the Vertebrates. By G. H. PARKER, Sc.D., Professor of Zoölogy, Harvard University. 192 pages. 37 illustrations. J. B. Lippincott & Company. Price \$2.50.

This book is one of the series of monographs on experimental biology edited by Jacques Loeb, T. Y. Morgan, and W. J. V. Osterhout. The writer presents, in a clear and readable style, a summary of all that is now known about these senses. The discussion of the details of the process whereby olfactory and gustatory sensations are aroused is particularly interesting. The book should be valuable as collateral reading in courses in physiology and psychology, and is well worth reading for its own sake, because it adds to one's store of general information.

A System of Clinical Medicine. By THOMAS DIXON SAVILL, M.D. 6th edition, 951 pages. Wm. Wood & Co., New York. 1922. Printed by Wm. Clowes & Sons, London and Beccles. 16mo.

A helpful and practical work on clinical diagnosis, prognosis and treatment, better known in Great Britain than in America. Etiology, pathology and the laboratory aspects of diagnosis are included. This sixth edition has been carefully revised and is up to date. As stated in the preface, this book differs from many current textbooks of medicine in that it approaches the subject from the point of view of symptomatology; thus differential diagnosis is a prominent feature. A vast amount of information is compressed into the volume, so that it serves as a guide to all aspects of clinical

medicine. However, in many instances, the information given comprises but useful hints so that other literature must be consulted to obtain desirable results.

There are four plates in colors and one hundred and seventy-two figures in the text. Such illustrations in most textbooks are unsatisfactory and those in this manual are no exception to the rule. However, the printing and publishing aspects of the book are pleasing.

Dr. Savill's book will fulfill many practical needs of the general practitioner and student, and if one is to have in his own library but a single volume on clinical medicine, this book would be a good choice.

The Place of Version in Obstetrics. By IRVING W. POTTER, M.D., F.A.C.S. With 42 illustrations. C. V. Mosby Co., St. Louis, Mo.

In this book of 130-odd pages, Dr. Potter has written a review of the early history of version, bringing it up to the present time. The main interest in the book and the real importance it has to the medical profession is his account of his so-called method of version.

Chapter four contains the author's technique of version. This chapter is to all intents and purposes a reprint of his article which appeared in the *American Journal of Obstetrics and Gynecology* for March, 1921. It contains the same photographs, with a few drawings added.

The reviewer will admit at the outset that Dr. Potter does the best version he has ever seen. His technique is interesting to see and in many instances physicians will profit by following it in doing a version. That the technique which he has developed is alone his, the reviewer can not agree with. It has been taught before that both feet should be brought down, it has been taught that the anterior arm should be delivered first, and more than one physician has elected to end labor by an elective version. But the reviewer knows of no physician who has taken the stand that every woman, if the physician can get to her before she delivers herself, should have a version performed upon her. Dr. Potter subjects every woman that he can to a version. Those that he can not deliver by version he does a Caesarean section on, with the result that in the last year, out of 1130 women that he delivered, 938 were delivered by version, and 100 by Caesarean section. Dr. Potter states that the procedure in competent hands should be attended with no maternal and a very small fetal mortality. Further on he says that the operation must at all times be done *only in properly selected cases* (his italics), and he quotes "The Potter version can be taught to students. It is easier to teach than the use of forceps." This last quotation is from an article by Rucker on "The Potter Version," published in the *American Journal of Obstetrics*

and Gynecology for March, 1921, and the fetal mortality in this series of cases ran from twelve to eighteen per cent.

This is what the reviewer feels will happen if the Potter method of delivery becomes widespread throughout the country. The mortality rate will rise and serious damage will be done to the children and to the mothers. Dr. Potter's only indication for performing a version is that he gets to the patient before she delivers herself. It is a dangerous teaching to put broadcast throughout the country, and it is in order to try to stop this wave of operating enthusiasm that the reviewer writes as he does.

DEFECTS IN SCHOOL CHILDREN.

BRUCE, R. (*British Medical Journal*, August 26, 1922), discussing defects of school children, comments on the fact that out of 15,000 school children examined there was no definite evidence of pulmonary tuberculosis and only seven suspected cases. This applies to definite tuberculosis of the lungs.

Tuberculosis of the bronchial glands and elsewhere was responsible for 9 per cent. of the total crippling of school children. [J. B. H.]

ADMINISTRATIVE REQUIREMENTS OF THE VARIOUS TYPES OF TUBERCULOSIS.

MACGREGOR, A. S. M. (*British Medical Journal*, August 26, 1922), takes up the requirements of the various types of tuberculosis from a Public Health point of view and considers the question of the administrative requirements of the patient who is definitely consumptive, particularly the ambulant chronic group. He calls attention to the lack of facilities for treating non-pulmonary forms of tuberculosis. [J. B. H.]

INDUSTRIAL FATIGUE AND VOCATIONAL SELECTION ON A BASIS OF PHYSICAL ENQUIRY.

McKAIL, D. (*British Medical Journal*, August 26, 1922), discussing the subject of industrial fatigue, summarizes his suggestions as follows:

Hours of labour: Spells of work to be normally two to three hours in all occupations demanding steady application and attention. In arduous work there must be rest spells after excessive exertions, and the latter must not be unduly prolonged.

Definite intervals for meals must be provided. For work starting before 9 a. m. two meal periods should be interposed in the time-table, owing to the fact that few persons take a normal amount of food in the morning, and it is too long to work a three or four hours spell before again getting food.

For the eight-hour day a three-spell day is therefore recommended, the first of two hours and two of three hours each. For a nine-hour day the first spell may be two and a half hours and the others three and a quarter hours each. If an industry can give a "living wage" on shorter hours this should be done, and the morning spell abolished.

Conditions of employment, especially in hazardous occupations, should be good. If such conditions cannot be secured, the industry should be suppressed.

Methods of work are worthy of study, to eliminate waste of energy, to find "best" methods, and to avoid harmful movements.

Vocational selection is at present limited to the "don'ts" department. Young persons with certain defects should not be permitted to engage in specified employments. [J. B. H.]

THE PELVIC APPENDIX.

MORISON, R. (*The Lancet*, September 9, 1922), discusses what he calls the "pelvic appendix," summarizing his remarks as follows:

Inflammation of the pelvic appendix can still mislead diagnostic experts. The ordinary symptoms of appendicitis—abdominal pain and fever—may both be absent in pelvic appendix cases.

The severe pain often attending appendicitis in the early stages, where the organ is situated, is due to tension within the appendix resulting from retention of its contents. During this period the symptoms are similar to those of acute intestinal obstruction.

Prolonged tension results in gangrene, when acute pain disappears until perforation occurs and a second variety of pain due to peritoneal irritation suddenly develops. In many pelvic appendix cases there is no severe early pain. Not until the appendix has perforated, generally at its distal end, are urgent symptoms noted. Absence of pain is not special to the pelvic appendix, but is more common in this than in any other variety. The explanation offered is that tension is not present, because this type of appendix can empty itself, and the first serious pain results from perforation.

Frequency of micturition, especially in boys, and in rare cases retention of urine, occurs as an early symptom.

Careful rectal examination may save the situation in a difficult case. So may a blood count.

Pelvic abscess may result from the localization of a diffuse peritoneal infection, from leaking of an abscess connected with the appendix in the right iliac fossa, or from a leaking pelvic appendix.

Rectal tenderness is the most suggestive symptom of a pelvic abscess.

The treatment of an inflamed pelvic appendix is to remove it as soon as a diagnosis has been made. After the second day from perforation it is seldom wise to operate from the abdomen, and this should never be done if the intestines are distended or the patient is acutely ill. Medical treatment is then the method of choice, until the abscess points in the rectum so prominently that it can be safely and easily opened there.

The normal peritoneum possesses an extraordinary natural immunity, but the importance of its acquired immunity is not yet appreciated fully.

Intestinal obstruction follows operations for pelvic appendicitis with disturbing frequency. When convalescence seems assured, during the second or third week, it develops suddenly. Early operation will save nearly every patient,—delay is deadly. Following abdominal operation for pelvic abscess a complicated faecal fistula may refuse to heal and threaten life. In women vaginal hysterectomy will save the majority of these dangerous cases. [J. B. H.]

BONE GRAFTING AS AN AID IN TREATMENT OF TUBERCULOUS SPINAL CARIES.

GRAY, H. M. W. (*British Medical Journal*, July 15, 1922), in an article excellently illustrated with numerous x-ray plates and photographs, discusses his method of bone grafting in tuberculous bone and joint disease. [J. B. H.]

BRAIN SURGERY.

MACWEN, W. (*British Medical Journal*, July 29, 1922), in his presidential address discusses the general subject of brain surgery in an able and scholarly manner. He takes up this subject from various points of view. This article is good reading, but does not permit of adequate review. [J. B. H.]

ALCOHOL AS A BEVERAGE AND ITS RELATION TO CERTAIN SOCIAL PROBLEMS.

MELLANBY, MOTT, MACCUBBY and others (*British Medical Journal*, August 5, 1922) discuss the subject of alcohol from various points of view. Mellanby considers it from its action on human economy; Mott takes it up in its relation to problems of mental disorders; while MacCurdy considers general etiological factors in the alcoholic psychoses.

These articles and their discussion are of interest and value.

SYMPOSIUM ON BONE SURGERY, FRACTURES, AND BONE REPAIR.

The entire number of the *Archives of Surgery*, Volume 5, Number 3, November, 1922, is devoted to twelve articles on the various aspects of bone pathology.

George D. Davis reports in detail a case of osteosclerosis fragilis generalisata with excellent x-ray plates of the whole bony skeleton. He refers briefly to the literature and instances a few other cases of this extremely rare condition.

Donald M. Glover reports an interesting case of osteosarthritis with excellent x-ray plates of the various fractures occurring in this one case.

Leroy C. Abbott of Ann Arbor makes an interesting report on the Bellet walking plaster for treatment of delayed union in fractures of both bones of the leg and shows a number of interesting x-rays which convince one of the feasibility of this method of treatment when operative interference is not desired or is contraindicated. He reports cases in detail.

Aflison and Brooks write an interesting article on bone atrophy, being a clinical study of the changes in bone which result from non-use.

Elie presents an extremely interesting study of the healing of fractures with numerous plates showing gross and microscopic appearance, and draws the following conclusions:

After an ordinary fracture, hemorrhage takes place from the marrow canal under the periosteum. The periosteum is stripped up from the cortex by this hemorrhage and by the fracture itself. Then comes the deposition of fibrin, the formation of granulation tissue and the formation of cartilage and fibrocartilage in the space beneath the stripped up periosteum. Probably the function of the periosteum is only important in the early stages, up to the formation of the cartilaginous callus. The periosteum probably serves to keep the hemorrhage from escaping and the granulation tissue undisturbed. It has no bone-forming function, and bone is not built out of it. The subsequent ossification of the cartilaginous callus is carried out almost entirely, if not exclusively, from the external aspect of the cortex. The internal callus plays no effective part in the union. It is rudimentary when it is present.

Whitman contributes an article on collective and

operative treatment of structural scoliosis, profusely illustrated, and draws the following conclusions:

1. Given a structural scoliosis of unknown origin in the case of an adolescent who applies for treatment because of progressive deformity, the prognosis as to the arrest of deformity is uncertain.

2. A certain number of such conditions may be held in check by apparatus and exercises, provided the patients at all times take a personal interest in their posture.

3. The only means of improving the actual deformity and the external appearance of the trunk is by apparatus embodying at least some of the principles outlined in the description of the corrective jacket.

4. The maximum degree of improvement having been obtained, the spine must be held corrected for a period of years while accommodative changes in the vertebrae take place.

5. This maintenance of correction can be effected only by a corrective jacket, reemulency, or operation.

6. As a climax to the corrective treatment, and as post-operative fixation, reemulency on the convex stretcher frame has proved effective in still further reducing the deformity of the ribs, and in allowing full opportunity for chest expansion.

7. While the amount of actual anatomic correction of the deformity of the vertebrae is exceedingly doubtful, the improvement in the patient's external appearance seems to have been maintained by the operation. It has also greatly abbreviated the period of their convalescence.

8. The older the patient, the more rapid the ankylosis.

Kleinberg writes on the operative treatment of scoliosis alone and believes that the discomfort and disadvantages of plaster of paris jackets are avoided and the physician is spared much hard work through the operative treatment. The final results obtained compare more than favorably with those following the use of plaster of paris braces or gymnastic exercises.

Baneroft contributes an excellent article on bone repair following trauma and infection, and draws the following conclusions from his work:

From the experience obtained with these cases and from the many animal experiments, I am convinced that, in the future in the treatment of children, we can be more conservative.

First, adequate drainage should be obtained with as little trauma as possible. Second, in cases in which the patient is clinically progressing favorably, bone, which by roentgen-ray or gross examination appears dead, may frequently be saved to advantage in order to prevent deformity and hasten convalescence.

Finally, I believe that in the past we have made bone repair appear much too complex. We have been lost in the by-ways of periosteum, endosteum and bone reticulum. It is much simpler to believe that bone occurs as a chemical deposition in connective tissue. Such a theory allows for bone formation as it appears in all parts of the body.

In bone transplants, we must assume that the transplant *per se* does not live, but that it acts as a framework for new bone and stimulates osteogenesis. We must, therefore, apply grafts that can easily have a blood supply established, and have sufficient free surface to stimulate bone production.

In the treatment of fractures, care must be taken to increase the blood supply. This is more important than immobilization that constricts the limb. Early motion favors union for this reason.

What we are apparently doing when a bone graft is made or when extra-skeletal bone occurs in an experiment is producing the right chemical state. Then the process of bone formation inevitably follows.

Lounsberry and Metz present an article beautifully illustrated with drawings on hiping fracture of the lower articular end of the tibia and show their end-results. [E. H. R.]

A REPORT OF FIVE UNUSUAL CASES OF HYPERTENSION IN PREGNANCY.

WILLIAMSON, A. C. (*Surgery, Gynecology and Obstetrics*, November, 1922), writes as follows:

Hypertension may exist throughout pregnancy with no apparent sign of kidney lesion.

Some cases of hypertension in pregnancy may be carried through to a successful termination with careful watching.

Cases in pregnancy with hypertension without demonstrable kidney lesions are probably of vascular origin.

The most likely cause of such hypertension is that it is of toxic origin with the primary action taking place directly in the arterial wall.

The prognosis of such cases is always grave and doubtful both for immediate and subsequent life and the patient should appreciate fully the import of hypertension. [E. H. R.]

SOME ERRORS IN THE DEVELOPMENT OF THE THYROID GLAND.

HARTLEY, J. N. J. (*Surgery, Gynecology and Obstetrics*, November, 1922), writes as follows:

Embryological researches have led to a better comprehension of the various congenital abnormalities encountered in the thyroid gland.

A lingual thyroid in many cases is a true ectopia thyroidea, and then represents the whole of the acting thyroid tissue of the body.

This is clinical confirmation of the modern embryological teaching that the thyroid derives no functioning tissue from the ultimobranchial body.

The absence of a palpable isthmus in the pre-tracheal region is strong evidence of such a lingual swelling being an ectopic and not an accessory thyroid.

When a lingual thyroid gives rise to symptoms demanding surgical intervention, a minimal amount of tissue should be removed, and the surgeon should be prepared to adopt thyroid therapy if the clinical symptoms or the basal metabolism rate indicate a state of hypothyroidism.

The so-called "infrahyoid" type of thyroglossal cyst not infrequently has an epithelial prolongation upward, either through, behind, or in front of the hyoid bone, and, to ensure non-recurrence, it is advisable, when the pedicle can be traced to this bone, to reset the middle portion and to search for a tract leading to the foramen caecum. [E. H. R.]

FRACTURES OF THE TIBIAL SPINE COMBINED WITH FRACTURES OF THE TUBEROSITIES OF THE TIBIA.

SEVER, J. W. (*Surgery, Gynecology and Obstetrics*, November, 1922), presents an interesting article on this latter rather rare condition. He finds that the condition is often discovered on close examination of x-ray plates of old lesions, that the lesion is often overlooked, the symptoms are more or less of a chronic nature, and the condition is also oftentimes discovered after a long lapse of time. The cases show a very good ultimate function after considerable time. Treatment has generally been non-operative, being by means of fixation and extension followed by massage and baking, and passive and active motion. No operation was done in the series reported. Operation should be reserved for cases which do not obtain full and free extension of the knee, especially where

there is pain and disability. The vertical incision through the patella is the technic of approach. [E. H. R.]

TUMORS OF THE TESTICLE, WITH ANALYSIS OF ONE HUNDRED ORIGINAL CASES.

TANNER, C. O. (*Surgery, Gynecology and Obstetrics*, November, 1922), writes as follows:

New-growth of the testicle occurs about once in 2000 male hospital admissions. The disease is practically always unilateral, involving both sides only as a metastatic growth from the skin, seminal vesicles, etc. Trauma as an etiological factor in these tumors evidently has some foundation. Practically all cases occur between the ages of 18 and 50 years, the period of greatest sexual activity. Both testicles are involved with about equal frequency. Undescended testicles within the canal are more apt to become malignant than normally placed organs. Undescended testicles within the abdomen are relatively immune to malignant changes. The average mortality of these tumors taken from literature is about 80 per cent., based on a four-year postoperative period. In this case the mortality was found to be about 70 per cent.

The so-called mixed type of tumor gives a much higher mortality than the carcinomatous type. In this series it was 90 per cent. in the former type and 60 per cent. in the latter. Tumors containing cartilage and squamous epithelium seem to have a decidedly unfavorable prognosis. The prognosis in abdominal tumors is also very bad—only 6 per cent. of a large series being alive and well two years after operation.

The radical operation should be performed in all cases in which the disease is apparently limited, i.e., in cases showing no abdominal metastases clinically. The ordinary castration operation, even when supplemented by Coley's serum, x-rays or radium, does not yield satisfactory results. [E. H. R.]

AN ARTICLE ON SYPHILIS OF THE UTERUS BY SOSNOWSKI.

SOSNOWSKI, J. C. (*Surgery, Gynecology and Obstetrics*, November, 1922), presents a fairly clear picture of a condition which it is believed may many times be overlooked and confused with pathological conditions in the uterus of a lesser severity. Undoubtedly the recognition of a syphilitic condition of the uterus with adequate treatment would cure a great many cases which now go on to invalidism without the true condition being recognized. The author states that the Wassermann reaction in many of these cases was negative and, therefore, the diagnosis was not confirmed by laboratory test; but, after some study, the clinical picture is generally fairly clear.

He speaks of the initial sore as not generally being on the cervix. If, however, it is on the cervix, we find this part of the organ rather soft, congested, with the ulcer surrounded by a bluish areola, and the ulcer covered with dirty looking membrane. The character of the discharge is serosanguineous. The second stage, or the stage of congestion and engorgement of the uterus, is called by the author the hyperplastic stage, or that of the wet uterus. The third stage, the hypoplastic or stage of the dry uterus, is the dormant stage. As the uterus passes through the wet stage, it is less and less apt to retain a foetus, and in the dry stage, it is almost impossible for a fertile ovum to find lodgment or nourishment in the fibrous-walled organ. This is the reason why abortion so often occurs in this type of uterus.

Given a combination of uterine symptoms with other evidences of syphilis, it is wise to try anti-syphilitic treatment before operative measures of any sort are instituted. [E. H. R.]

OVARIAN TRANSPLANTATION.

MARTIN, F. H. (*Surgery, Gynecology and Obstetrics*, November, 1922), writes as follows:

My first report was made in 1903; my second report in 1908; my third in 1911; my fourth in 1915; my fifth in 1917. As in this, my sixth report, I have attempted each time to bring the literature up to date, and to furnish a complete bibliography.

I can summarize my impression of the whole subject by saying that as more evidence is accumulated from the literature, the claim of the earlier enthusiasts seems to become less and less substantial.

The one most hopeful feature that I am able to glean from the mass of more or less loosely recorded evidence is that the clinical records dealing with transplantation in the human show that while autotransplants give some evidence of success, homotransplants and heterotransplants give practically none at all. On the other hand, definite evidence of success is recorded as the result of carefully conducted experiments on animals in which matters of selection of appropriate material and proper technique are more controllable than in dealing with the human. May we hope that this fact and a more careful study of the subject from a scientific and experimental standpoint will reverse the unsatisfactory showing?

In the meantime, in the light of previous publications, the opinions expressed in the writings on this subject in 1918, 1919, 1920, and 1921, may be summarized as follows:

1. Clinically, there is very little to encourage one to believe that transplantation of ovaries as practised up to the present time has more than speculative value as a surgical procedure.
2. There is some evidence that autotransplants are of some value in deferring the symptoms of the menopause and delaying the cessation of menstruation. It is difficult, however, not to attribute some of this evidence to suggestive therapeutics or to unattached ovarian tissue left *in situ*.
3. There is practically no convincing evidence that homotransplants have been successful in the human female.
4. There is no evidence that heterotransplants have been successful where the human female has been the recipient.
5. There is some encouraging evidence recorded in experimental animal surgery that not only autotransplants, but homotransplants, and even heterotransplants have been successful and the sexual function of the castrated animal maintained.
6. The technique followed by the various operators on human females, in too many instances, seems unsurgical and too often is incompletely and loosely recorded, leaving the impression that the conclusions derived from such work must be unreliable.
7. There is, however, encouraging evidence in all of this endeavor to lead one to hope that the subject will be pursued experimentally, especially for the purpose of devising a rational and simple technique, based on the work of the serologists, the endocrinologists, the haematologists, and the practical clinical surgeons. [E. H. R.]

PELVIC TUMORS WITH SACRAL ATTACHMENTS.

LAW, A. A. (*Surgery, Gynecology and Obstetrics*, November, 1922), states that, owing to the demonstrated tendency to malignant degeneration, these tumors should be removed when recognized and that they always should be attacked from behind through the sacro-coccygeal route. The modified Kraske approach is ideal for the larger tumors, which permits them to be shelled out with little difficulty, usually

without invading the peritoneum, and facilitates the control of hemorrhage. The author reports two cases. [E. H. R.]

OBSERVATIONS ON THE TREATMENT OF SYPHILIS IN PREGNANCY IN THE DEPARTMENT OF HEALTH IN DETROIT.

WELZ and VAN NEST (*American Journal of Obstetrics and Gynecology*, Vol. IV, No. 2, August, 1922) state that most obstetricians find that the greatest causative factor in premature deliveries and macerated feti is syphilis. At Prenatal I of the Department of Health of Detroit an attempt has been made to lessen the incidence of congenital syphilis through prenatal care. During 1921, 1167 new prenatal cases attended the clinic. Of them, 47.6 per cent. were white and 52.4 per cent. were colored. Of the total, 13.1 per cent. were diagnosed as syphilitic. Among the white patients, 5.7 per cent. were syphilitic, and among the colored, 19.3 per cent. were syphilitic. Of the total of 193 patients having syphilis, only 147 were cared for through pregnancy. The following conclusions were made:

About 85 per cent. of the mothers diagnosed as syphilitic suffered from latent syphilis. It was not through complaint, but through routine examination that these were discovered.

Early diagnosis and treatment are of utmost importance. As syphilis is transmitted only through the placenta to the fetus after a period of about three months, it is evident that treatment instituted early in pregnancy can prevent fetal transmission. After the fetus is infected, the possibility of fetal cure is lessened and it is more difficult to accomplish. It is questionable whether antisyphilitic treatment through the mother can be of any value to the fetus *in utero* when the vital organs of the fetus are severely involved. Full treatment should be attempted even at the end of pregnancy in hope of securing a controlled case in a living child which can be further cared for after birth.

The injection of neosalvarsan was not found to produce miscarriages or premature deliveries. With a small initial dosage, gm. 0.3, and an increase to gm. 0.45 or gm. 0.6 in weekly injections, no harm results.

Those mothers who have not completed their treatment before delivery are urged to return for the completion of treatment after delivery. They are also urged to return to the clinic for examinations and care as soon as future pregnancies are suspected.

Every prenatal case should be carefully examined for syphilis. Routine examinations of placenta and fetus for signs of syphilis are valuable not only to the child, but to subsequent children which are born after proper treatment has been instituted upon the mother. [H. G.]

INFLUENCE OF GLANDS WITH INTERNAL SECRETIONS ON THE RESPIRATORY EXCHANGE.

MARINE, D., and BAUMANN, E. J. (*Journal of Metabolic Research*, June, 1922, Vol. I, page 777), gave nine experiments from which they concluded that a thyroid-suprarenal cortex interrelationship exists, which is separate from the thyroid chromophil tissue interrelationship. The nature of this relationship is unknown, but the evidence suggests that the suprarenal cortex, as one of its functions, exercises an inhibitory or regulatory control over thyroid activity. They also believed that these observations throw light on the thyroid-sex gland interrelationship known since antiquity and probably have an important bearing both on the etiology of simple goitre and on exophthalmic goitre. [H. G.]

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

AN "OPEN LETTER."

A so-called "Open Letter" has been sent to "School Committees, Principals and Teachers" by the Medical Liberty League, Inc. This letter concerns the Schick test, and urges its recipients, before aiding or abetting the efforts of propagandists of the Schick test, or consenting to take any part in conducting Schick test clinics in the schools under their control, to make their own investigation "as to the alleged merits of this much advertised procedure."

An open letter, apparently, is not necessarily the product of an open mind, for the initial statement is followed by four printed pages of violently anti-Schick propaganda. The unfortunate cases of Dallas, Texas, of 1919, where an improperly made proprietary preparation of toxin-antitoxin caused severe reactions and five deaths, and the experience of Macon, Georgia, in the same year, are cited. It is interesting as regards this second experience to note that the statements of injuries as read in the plaintiffs' petitions only are quoted.

These statements are followed by a number of others, probably accurately quoted, but, as is the custom of these writers of open letters, so misconstrued or robbed of their context as to imply a meaning that was not intended by their authors in most instances.

It is not our purpose to argue point by point

the conclusions reached by our opponents. The Schick test and toxin-antitoxin have been accepted by the medical profession, that body of men which is, by and large, most capable of passing on their merits. The Schick test and toxin-antitoxin, as with all justifiable medical procedures, are not infallible. The Schick test may be in error; toxin-antitoxin may fail to immunize; the patient with acute appendicitis may die under the knife. Nevertheless, all of these procedures are justifiable. Where we lay ourselves most open to criticism, granted that our products are carefully prepared and our technique scrupulously performed, comes in promising too much for our performances.

We must accept the methods for well-doing that are provided us, acknowledging their failures and liability to error, promising too little rather than too much; then, having formed our opinion as to their value, stand behind them to the limit of their worth, for only in this way can we, who are entrusted with the public safety, successfully combat the forces of ignorance, prejudice, or malice.

THE ANNUAL REPORT OF THE COMMISSIONER OF PUBLIC HEALTH.

This résumé of the conditions met and activities maintained is gratifying to students of health problems because this report presents evidence of progress in this important department of public service.

The loss of three devoted public servants through the deaths of Dr. William J. Gallivan, Prof. William T. Sedgwick, and Mr. James C. Coffey has been a serious one to this department.

All divisions of the department are now in charge of full-time expert officials.

1921 has no parallel in the history of the Commonwealth in its freedom from epidemics. One typhoid epidemic, due to infection of a single unpasteurized milk supply, practically covers the entire story of serious epidemics for the year! There were 114 cases in this outbreak.

The number of deaths caused by pulmonary tuberculosis during 1921 throughout the entire state will not exceed 3,300, which is at a rate of about 85 deaths per 100,000—a reduction of 38 per cent. since 1918.

Instead of expanding the organization concerned with control of venereal diseases, as had been planned, the department was forced to cut down expenditures in this direction because of the cessation of Federal funds for the furtherance of venereal disease work in the several states. The attendance at venereal clinics is increasing, but the Massachusetts Charitable Eye and Ear Infirmary workers report an increase in cases of congenital eye syphilis. The crying need in this work is for follow-up workers. (1) To discover fresh foci; (2) To get in-

feeted persons under treatment as soon as possible, and (3) To see that these individuals persist in treatment until benefit is assured.

The lepers formerly at the leprosarium on Penikese Island have been transferred to the new Federal leprosarium at Carville, Louisiana. The closing of the state leprosarium is the outstanding institutional feature of the year.

The following recommendations for legislation have been submitted to the General Court:

1. An act accepting the provisions of an act of Congress relative to the promotion of the welfare and hygiene of maternity and infancy and for other purposes and providing for cooperation with the Federal government.

2. An act relative to the analysis of liquor by the Department of Public Health.

3. An act relative to the publication of certain information by the Department of Public Health.

4. An act relative to the examination of vinegar.

5. An act relative to the purchase of land in Westfield.

6. A resolve relative to the reappropriation of certain funds to be used in connection with the work of the sanitary improvement of the Neponset River.

It is interesting to note that the percentage of deaths of six of the more common communicable diseases to the death rate from all causes for the last forty years is decreasing.

Hookworm	1	—
Typhus fever	2	1
Total	77,302	7,621

¹ Made reportable March 1.

For the work of the Subdivision of Venereal Diseases the following table, showing the figures for 1919, 1920 and 1921, indicates at a glance the continued progress in this field:—

	1919.	1920.	1921.
Ampoules of arsphenamine distributed	21,667	26,782	38,473
Cases reported by number:			
Gonorrhea	9,435	7,225	5,568
Syphilis	4,127	2,986	2,497
Pamphlets distributed	21,762	59,280	37,802
Smear examinations	4,035	2,815	2,478
Wassermann examinations	32,390	37,207	42,957
Figures for all State-approved clinics:			
New patients	4,492	7,314	4,197
Total treatments	19,005	142,367	98,473
Lapsed cases:			
Reported	1,421 ¹	1,344	1,147
Returned to treatment	616	365	327

¹ Cases reported by name from State institutions are included with the lapsed cases up to April, 1919.

HISTORICAL LIGHT ON THE SUBJECT OF BIRTH CONTROL.

The sociologic problem of birth control is being seriously considered in many countries. In the United States the people have dealt with it quite definitely, whereas in England, for example, certain phases of it are being discussed in a way which would lead to the suspicion that the public mind has not yet been developed to the point of a definite conclusion. An English editor* gives us the following statistical information, which, we admit, piques our historical curiosity to know more about these famous men: but why does he descend from the philosophical peak of putting to us an unanswerable scientific question?

"So far as the mental side is concerned, history gives us facts concerning the parental age which is most favorable to the production of the best offspring. Shakespeare was the third child; Tennyson, the third son; Michael Angelo, the second son; Beethoven, the second of five sons and two daughters; Cromwell, the second son; Kant, the second of nine children; Newton, the only child; Darwin, the youngest but one of six children; Lyell, the eldest son; Goethe, the eld-

*Medical Press.

est child; Wellington, the third son; Robert Blake, the eldest of thirteen sons and two daughters; Chatham, the second son; Burke, the second son; Swift, the second child; Gibbon, the eldest of five brothers, and Dickens, the eldest of eight. Bacon was the youngest son; Carlyle, the eldest of nine children; Gladstone, the youngest son; Clive, the eldest son; Warren Hastings, an only child.

In this casual list the intellectual prodigy was the eldest son in nine out of the twenty-two, *i.e.*, Shakespeare, Carlyle, Newton, Goethe, Robert Blake, Clive, Warren Hastings, Gibbon and Dickens. Seven others were second children.

Among the nine eldest sons Shakespeare and Newton are the outstanding great men. However, Shakespeare, being a third child, would not have lived if only two children had been born to the elder Shakespeares. The same statement holds true in regard to Darwin, Wellington and Gladstone, as well as to Bacon, who was the youngest, and to Tennyson, who was the third son.

How would the pages of history have been altered if biological laws had been interfered with in these cases?"

These figures obviously cannot be taken seriously in considering the subject of birth control from a scientific standpoint. They deserve a sentimental interest only—and such we give them with enthusiasm.

DARWINISM VERSUS CHRISTIANITY AGAIN.

At a recent conference in St. Paul, Minnesota, of pastors representing Baptist, Congregational, Presbyterian and Lutheran churches, it was decided to issue a call for a state-wide meeting of Protestant ministers to oppose the teaching of evolution in the public schools of Minnesota.

The resolutions passed closed with the following paragraph:

"And we declare that if school authorities prove derelict in the enforcement of the law relating to the teaching of religion or of theories subversive of the Christian faith, we will appeal to the legislature for the enactment of such laws as shall eliminate from our tax-supported school system this antiscientific and antisciptural theory of the origin of man and the universe."

Although there may be difference of opinion relating to the theories of evolution it is open to question whether the decision relating to the interpretation of scientific data should be left with the clergy, for there is not sufficient evidence at the present time indicative of an adequate amount of study on the part of the clergy that would warrant leaving the interpretation of the evidence to this body of men.

Furthermore, many scientific minds have not found in the theory of evolution any conflict with religious teaching.

AN ALLEGED ABORTIONIST DISCIPLINED BY THE COURT.

The daily papers report that Dr. Alfred D. Shea, of Cambridge, pleaded "nolo contendere" November 21, 1922, when arraigned in the Superior Criminal Court, charged with performing an illegal operation on a girl.

The Judge, according to the reports, placed Dr. Shea on probation for three years, with the condition that Dr. Shea shall not again engage in practice in this State.

In May, 1912, Dr. Shea was convicted on a charge of criminal abortion and sentenced to a term in prison of not more than 10 years, and not less than 7 years. He was pardoned by the Governor and Council the following December. Upon suspicion he was under investigation in another similar case, but through questions of legal technicality was not brought to trial.

It is gratifying to learn that this dishonored physician cannot pose as a member of the profession. The condition imposed by the Judge is an unusual way of dealing with this form of irregular practice and will have a good effect.

DIAGNOSTIC SERVICE FOR TROPICAL AND EXOTIC DISEASES.

The Department of Tropical Medicine of the Harvard Medical School has organized, for the service of the public through the medical profession generally, a diagnostic laboratory affiliated with the Service for Tropical Diseases at the Boston City Hospital.

So far as the nature of the particular problem allows, final reports will be rendered on material sent to the Department of Tropical Medicine. When it is not practicable to make the diagnosis from material that can be sent, and the presence of the patient is necessary, unless the Health Department should deem it advisable to place the case elsewhere, the patient can be referred to the Service for Tropical Diseases at the Boston City Hospital, where the necessary examination will be made either in the Out-Patient Department (Tuesday or Thursday mornings) or after admission to the ward-beds of the Service for Tropical Diseases. The necessary diagnostic procedures will then be carried on either at the Boston City Hospital or at the Harvard Medical School through the agency of the Department of Tropical Medicine.

A list of diseases in regard to which the Department of Tropical Medicine is prepared to advise as to prevention or diagnosis follows.

In a parallel column the appropriate laboratory methods of diagnoses are indicated.

Physicians are invited to write or to telephone to the Department of Tropical Medicine for information about its diagnostic service or about the best methods of obtaining material for examination.

TROPICAL AND EXOTIC DISEASES.

(Diseases printed in italics have been found in Massachusetts.)

SECTION I: PROTOZOAN DISEASES AND DIAGNOSTIC METHODS.

1. Malaria: *tertian*, *subtertian*, *quartan*. Examination of blood smears or fresh blood preparations.

2. Trypanosomiasis: *African Sleeping Sickness*. Animal inoculations. Chagas Fever (South American Trypanosomiasis). Examination of blood smears or fresh blood preparations. Spinal fluid.

3. Leishmaniasis: *Kala azar*. Animal inoculations. *Oriental sore*. Examination of scrapings from lesions. American Leishmaniasis. Examination of sections of tissue.

4. *Amoebiasis*. Examination of fresh faeces.
5. Infection with: (a) *Balantidium coli*. (b) *Giardia intestinalis* (lamblia). (c) *Trichomonas intestinalis* (trichomonas). (d) *Chilomastix mesnili*. Examination of fresh faeces.

SECTION II: SPIROCHETAL DISEASES AND DIAGNOSTIC METHODS.

1. *Yaws*. Examination with dark field of serum from lesions and of stained preparations.

2. *Relapsing Fever*. Examination of fresh blood preparations and stained smears. Animal inoculations.

3. *Rat-bite Fever*. Dark field examination of fresh blood and of stained specimens.

4. Infectious Jaundice. Animal inoculations. Agglutination test with patient's blood. Urine examination.

5. *Yellow Fever*. Animal inoculations. Serum reactions. Examination of fresh blood and stained preparations.

SECTION III: BACTERIAL INFECTIONS AND DIAGNOSTIC METHODS.

1. Plague. Examination of blood cultures and cultures from material from gland puncture. Animal inoculations.

2. Tularensis infection (deer-fly fever). Examination of cultures of blood and material from glands. Animal inoculations.

3. *Undulant Fever*. Examination of blood cultures. Agglutination test.

4. *Bacterial Dysentery*. Examination of cultures from faeces. Agglutination test.

5. *Cholera*. Examination of cultures from faeces. Agglutination test. Pfeiffer's reaction.

6. *Leprosy*. Microscopical examination of nasal secretion and scrapings from lesions.

SECTION IV: INFECTIONS OF UNKNOWN ETIOLOGY AND DIAGNOSTIC METHODS.

1. *Typhus Fever*. Agglutination reaction of Weil-Felix. Pathological examination of skin.

2. Rocky Mt. Spotted Fever. Animal inoculations with blood.

3. Inguinal Granuloma. Examination of smears from lesions. Examination of sections of tissues.

4. *Tropical Phagedena*. Examination of smears from lesions. Examination of sections of tissues.

5. Veldt sore. Examination of smears from lesions. Examination of sections of tissues.

SECTION V: MYCETOMA AND DIAGNOSTIC METHODS.

1. *Madura Foot*. 2. *Blastomycosis*. Microscopical examination of fresh and stained preparations from lesions.

3. Sporotrichosis. Cultures from lesions.

SECTION VI: PARASITIC INFECTIONS AND DIAGNOSTIC METHODS.

1. *Filariasis*. (a) *Filaria bancrofti* (endemic elephantiasis). Examination of fresh and stained blood preparations. (b) *Filaria loa* (diurna). Examination of fresh and stained blood preparations. (c) *Onchocerca volvulus* (filaria volvulus). Examination of fresh and stained blood preparations, and examination of sections of lesions.

2. *Distomiasis*. (a) Paragonimiasis (endemic hemoptysis). Examination of sputum for ova. (b) Schistomiasis. I. *Schistosomum hematobium* (vesical bilharzia). Examination of urine or faeces for ova. II. *Schistosomum mansoni* (rectal bilharzia). III. *Schistosomum japonicum*. Complement-fixation test with blood. (c) *Clonorchiosis*. Examination of faeces for ova. (d) Other liver flukes. I. *Fasciolopsis buski*. Examination of faeces for ova. II. *Fasciola hepatica*. Examination of faeces for ova.

3. *Ankylostomiasis* (Hookworm, Uncinariasis). Examination of faeces for ova or parasites.

4. *Tacnia Infections*. *T. Echinococcus*. Examination of pathological material. Agglutination test. *Dibothriocephalus* (Fish Tapeworm). *T. Nana* (Dwarf Tapeworm). Examination of faeces for ova. Identification of parasites.

5. *Strongyloides*. Examination of faeces.

6. *Myiasis* of Nose, of Ear, of Gastro-intestinal tract. Examination of discharges and identification of larvae.

SECTION VII: OTHER DISEASES OF INTEREST TO THE DEPARTMENT.

1—*Sporadic elephantiasis*. 2—*Heat-stroke*, heat exhaustion. 3—*Siriasis*. 4—*Berberi*. 5—*Scurvy*. 6—*Pellagra*. 7—*Sprue*. 8—*Small-pox*. 9—*Dengue*. 10—*Chiggers Disease*. 11—*Acarine dermatomycosis*. 12—*Oroya Fever*. 13—*Verruga Peruiana*. 14—*Japanese River Fever* (Tsutsugamushi fever). 15—*Pappataci* or *Phlebotomus Fever*. 16—*Black-water Fever*. 17—*Dracunculiasis* (Guinea-worm disease).

GEORGE C. SHATTUCK, M.D.

News Notes.

FRANKLIN DISTRICT MEDICAL SOCIETY.—The November meeting was held at the Weldon, Tuesday, November 14, 1922. Programme: "Along the Byways," Dr. W. A. Hutton, Shelburne Falls. "The Bright Child and the Dull," Dr. Walter C. Fernald, Waverley, Mass.

DEATH RATE IN BOSTON.—During the week ending November 18, 1922, the number of deaths reported was 221 against 203 last year, with a rate of 15.09. There were 27 deaths under one year of age against 22 last year. The number of cases of principal reportable diseases were: Diphtheria 70, Scarlet Fever 35, Measles 63, Whooping Cough 70, Typhoid Fever 4, Tuberculosis 43. Included in the above, were the following cases of non-residents: Diphtheria 8, Scarlet Fever 8, Whooping Cough 1, Tuberculosis 8. Total deaths from these diseases were: Diphtheria 3, Measles, 1, Whooping Cough 3, Tuberculosis 8. Included in the above, were the following cases of non-residents: Tuberculosis 2.

THE UNIVERSITY OF ROCHESTER is completing this month the first building for the new medical school. The City of Rochester has appropriated \$1,000,000 for the new City Hospital to adjoin the Strong Memorial Hospital. The University is to furnish the professional staff for these combined hospitals, which will have capacity for 460 beds.

DR. FRANCIS W. PEABODY read a paper Nov. 21, 1922, before the Section of Medicine of the New York Academy of Medicine under the title, "The Patient and the Man."

CHANGE OF OFFICES.—George David Cutler, M.D., and Ernest T. Saeger, M.D., announce the removal of their offices to 270 Commonwealth Avenue, Boston. Telephone Back Bay 1520. Patients seen by appointment.

GRADUATING EXERCISES OF THE SCHOOL OF NURSING OF THE PETER BENT BRIGHAM HOSPITAL.—On November 10, 1922, thirty nurses received diplomas as graduates of the Peter Bent Brigham School of Nursing. Professor C. E. A. Winslow of Yale University delivered an address and Miss Hall gave a report of the work done in the school. The exercises closed with a reception.

THE PASTEUR LECTURE FOR 1922 of the Institute of Medicine of Chicago was delivered by Dr. Jacques Loeb, of the Rockefeller Institute, on Friday, November 24, 1922.

DR. JAMES EWING, Professor of Pathology at Cornell University Medical College, New York, addressed the College of Physicians of Philadelphia, on November 1. His subject was "The Principles of the Radiation Treatment of Cancer."

DR. ROBERT BÁRÁNY, Professor of Otology at the University of Upsala, Sweden, and winner of the Nobel Prize in Medicine in 1914, is touring the United States, stopping in each of the larger cities to lecture before otologists and ophthalmologists. He gives a two weeks' lecture course and several clinics. His itinerary includes Chicago, Denver, Los Angeles, Houston, Cincinnati, Cleveland, Boston, and New York.

THE SALVATION ARMY ROXBURY HOSPITAL invitations were issued for the opening exercises to be held at the hospital, 87 Vernon street, on Thursday evening, November 23, at eight o'clock. Addresses were delivered by Colonel W. A. McIntyre, Salvation Army, and Dr. J. A. Cousens, President Tufts College.

DR. SELIG HECHT, national research fellow in chemistry, has been appointed research fellow in physical chemistry at the Harvard Medical School, where he will continue his investigations.

DR. ARTHUR BLISS DAYTON, associate in medicine at the Yale School of Medicine, has been given a year's leave of absence to serve as Professor of Medicine at the Medical School of Yale-in-China.

MR. JOHN D. ROCKEFELLER in a recent communication to the directors of the University of Cincinnati, objecting to the plan of naming a chair in the College of Medicine, says, "I should prefer to have my name recorded in the hearts and lives of those using the improvements which donations from me have made possible rather than have it carved in stone or officially connected with the building."

AMERICAN SURGICAL ASSOCIATION.—The next meeting will be held at Rochester, Minnesota, January, 1923.

The officers elected at the annual meeting are President, Dr. Lewis L. McArthur, Chicago; Vice-Presidents, Dr. Ellsworth Eliot, Jr., New York; Dr. Donald C. Balfour, Rochester, Minnesota; Secretary, Dr. Robert B. Greenough, Boston; Treasurer, Dr. Charles H. Peck, New York.

BOSTON MEDICAL HISTORY CLUB.

The first meeting of the season was held at the Medical Library on Nov. 17, and it was voted to hold future meetings on the third Mondays of each month through April.

In commemoration of the third centenary of Molière's birth (1622), Dr. Joseph W. Courtney read a paper on "Molière and the Faculty." His paper was a careful study of medical conditions in France at this period, with especial emphasis on the co-called Faculty of Medicine in Paris, its pedantry, jealousy of other schools, ignorance, and its downfall, greatly hastened by Molière's satire.

Many local allusions in the text of the plays were explained and various characters identified with well known doctors of the time. Extracts from the plays, translated into delightful colloquial English by the reader, gave great pleasure and an added realization of Molière's skill and power, and his tragic end was vividly sketched.

Following the paper, books, pictures and articles published in medical literature having to do with Molière were shown by various members of the club.

The next meeting, to be held Monday, Dec. 18, will be devoted in part to Pasteur, the centenary of whose birth occurs on Dec. 27.

CANCER DEATH RATE.

According to statements made by Mr. Edgar A. Bowers, State Registrar of Vital Statistics, the deaths from this disease since July 1, 1922, indicate that the rate will equal that of the first six months of this year and that the present rate is about the same as for 1921.

There were 2334 deaths from cancer during the first six months of this year, divided as follows: males, 899, and females, 1435. Based on the estimated population of Massachusetts this means an annual death rate in this state of 119.6 per 100,000 population. The rate for 1921 was 119.5.

BEVERLY HOSPITAL CLINIC.

A clinic was held at the Beverly Hospital, Thursday, Nov. 16, at 4 p.m., in observation of "Cancer Week."

Dr. Channing Frothingham of the Peter Bent Brigham Hospital, Boston, was the first speaker, the subject being, "Early Diagnosis of Cancer." He specially stressed the importance of thorough investigation by both patient and doctor of the cause of pain or bleeding in any part of the body.

Dr. P. P. Johnson, Chief of the Surgical Staff of the Beverly Hospital, reviewed the year's cases of cancer at the Hospital. This review brought out most strikingly the fact that too long a time elapsed between the recognition of symptoms and operation.

Dr. Isobel Bogan, Roentgenologist at the Beverly Hospital, showed interesting x-ray pictures of cancer and brought out the fact of the great aid that the x-ray gave in the early recognition of cancer in all parts of the body. She also emphasized the importance of using this aid of diagnosis more frequently and earlier.

Dr. W. T. Hopkins, of Lynn, discussed the papers and pointed to the importance of the earlier recognition of symptoms of cancer by the patient, and the importance of consulting the doctor earlier and insisting on a thorough examination.

NEW ENGLAND DERMATOLOGICAL SOCIETY.

At the quarterly meeting of the New England Dermatological Society on October 11, 1922, at the Massachusetts General Hospital, the following cases were shown:

1. Young woman; pigmented areas on face, possibly from application of face cream containing mercury. Dr. C. M. Casselberry.
2. Young woman; late syphilitic lesions of the face. Dr. C. M. Smith.
3. Case for diagnosis. Man, 43 years old, fisherman; nodular lesion at the left corner of mouth; duration, five months. Low grade infection, syphilis, sarcoid, and tuberculosis considered. Dr. A. M. Greenwood.
4. Man, 50 years old, a farm worker, with actinomycosis of skin over right jaw. Dr. J. H. Blaisdell.
5. Man, 39 years old, who had taken considerable Fowler's solution, showing keratoses and epithelioma, probably arsenical in origin. Dr. A. M. Greenwood.
6. A baby, 22 months old, showing persistent crops of bullous lesions. Pemphigus or dermatitis herpetiformis. Dr. L. J. Cummins.
7. Case for diagnosis. A woman, 27 years old, with persistent, curious erythematous and

popular eruption. Poikiloderma atrophicans vasculare (?). Dr. C. G. Lane.

8. Man, 47 years old; itching papular eruption for two years; glands in neck; x-ray shows substernal mass. Hodgkin's disease. Dr. C. G. Lane.

9. Man, 68 years old; general exfoliative dermatitis. Dr. C. G. Lane.

WORCESTER STATE HOSPITAL TRAINING SCHOOL FOR NURSES.

Dr. William A. Bryan, Superintendent, has issued a circular setting forth the need for nurses in the training school connected with the Worcester State Hospital. The entrance requirements and the details of training are set forth as follows:—

"Candidates must be at least eighteen years of age and have the equivalent of one year of High School. We offer a three years' course of approved instruction and with much practical work in general nursing. The second year the student spends at the Boston City Hospital, where she receives instruction in contagious diseases, care of children, obstetrics and general medical and surgical nursing. In our own hospital, we give an excellent training in general nursing, having active services in all specialties. In addition, nurses receive thorough instruction in occupational therapy, hydrotherapy, mechanical therapy and experience in mental work."

The wages paid the nurses and the opportunities for attendants are also set forth in the circular as follows:—

"Pupil nurses receive in addition to their board, room and laundry, \$40 per month, which is increased to \$50 at the end of the first year. Nurses are allowed 3 hours off duty each day, and one full day each week, and two weeks' vacation each year with pay. Head nurses receive from \$65 to \$75, with maintenance. We can also use a number of women attendants, who will be given an attendant's course in practical nursing. The pay of the attendants is \$40-\$50, and promotion to the grade of charge attendant carries an increase from \$55 to \$65."

THE BENEFITS OF PUBLICITY.

The lectures given during cancer week have aroused considerable interest. The free clinics have been well attended and many persons have been given expert advice. Surgeons will remove many cancers in the early stages, thereby saving many years of life as a result of the information disseminated.

Dr. Wolbach submits the subjoined letter which demonstrates one of the results of publicity. The name of the writer is omitted because the JOURNAL does not lend itself to this form of advertising.

Dr. Wolbach has not yet recommended this man for a position on the faculty of a medical school, or the department of pathology connected with any of our hospitals.

Nov. 17, 1922.

Sir.—With reference to your lecture on Cancer, reported in the Boston *Globe* of the 13th inst., I wish to inform you that I make a salve which cures all known skin troubles, including piles, cancer, and blood poison. In the above-named cases it has done the knife out of many a job. Want of finance prevents me from bringing it properly under public notice, and having it tested on what is called leprosy, which I will be in a position to do later. There are five ingredients in it, two of which are red and white precipitate powders. If you think it will help you in any way please let me know. Yours truly.

MEMBERSHIP IN THE HARVARD MEDICAL ALUMNI ASSOCIATION.

At a meeting of the Harvard Medical Alumni Association, held in the faculty room of the Harvard Medical School on November 20, the recommendation of the Council that "Section 1, Article 3, of the constitution be amended to read: 'Each graduate of the Harvard Medical School shall become *ipso facto* a member of the Harvard Medical Alumni Association.'" was approved. Also the recommendation that Section 4, Article 3, be amended by adding the following sentence: "All members of the teaching staff of the Harvard Medical School shall, during their term of service, be considered honorary members of the Harvard Medical Alumni Association." was approved.

FRANCIS M. RACKEMANN, M.D., *Secretary*.

MOTHERCRAFT CONFERENCE IN BOSTON.

A Mothercraft and Child Welfare Conference is to be held in Boston on Tuesday, December 5, under the auspices of the Massachusetts Federation of Women's Clubs. There will be a morning session at the Exeter Theatre at 10.45, for which the tickets will be complimentary; a luncheon at Hotel Lenox for delegates at 12.45, and at 4.30 an informal reception in the Fine Arts Department of the Boston Public Library, which will be the opening of a child welfare exhibit to be on view during the week. A feature of the meeting in the Exeter Theatre will be the first showing here of the mothercraft film. The speakers will include Mrs. Grace Morrison Poole, President of the Massachusetts Federation; Mrs. Elmer Blair and Mrs. Ira Couch Wood, high officers in the General Federation; Dr. A. E. Winship, representing edu-

cation; Mrs. E. C. Hanington, Superintendent of the Victorian Order of Nurses, Canada; Dr. Allan J. McLaughlin of the U. S. Public Health Service; Dr. John B. Hawes, 2d, of the Boston Tuberculosis Association; Dr. M. E. Champion, representing the State Department of Public Health, and others. Miss May Bliss Dickinson is Chairman of the Conference.

MORE COMMERCIAL VITAMINES.

The daily papers are announcing the discovery of a new process perfected by scientists of Yale, Harvard, Johns Hopkins, Penn. State, Mellon Institute of Industrial Research, and other American Universities, working in conjunction with a group of chemists employed by George S. Ward, millionaire baker. A vitaminine syrup has been produced which can be combined with white bread, restoring to it the necessary food elements lost in the refinement of the flour.

Dr. Reid Hunt, of the Harvard Medical School, disclaims any connection with this work, classing it with the other attempts to commercialize the vitamins. According to his suggestion, more would be gained by advising people to add bran to their cereals and drink milk.

DEMONSTRATION CLINIC AT THE BEVERLY HOSPITAL.

A demonstration clinical meeting was held at the Beverly Hospital, Tuesday, Nov. 21.

Dr. P. P. Johnson, chief of the Surgical Staff, showed the following cases: Abdominal pain, abscess left shoulder, intestinal obstruction, appendicitis with abscess and bone tuberculosis.

Dr. Buck of the Medical Staff spoke on renal function test and showed a case of abdominal pain with a question of acidosis.

Dr. Hopkins of Lynn and Dr. Pettingill of Essex Sanatorium discussed cases.

Doctors were present from Beverly, Danvers, Hathorne, Middleton, Hamilton, Lynn and Topsfield.

R. E. STONE,
Secretary of Staff.

MASSACHUSETTS ASSOCIATION OF ASSISTANT PHYSICIANS.

The 57th meeting of the Massachusetts Association of Assistant Physicians was held at the Boston State Hospital on Thursday, November 16, 1922, seventy-eight members and their wives being the guests of the superintendent, Dr. James V. May.

During the morning small parties were escorted through the institution by members of the staff and given the opportunity of seeing the many interesting features of the hospital.

The ladies of the party were entertained by the hostess, Mrs. E. C. Noble, while the meeting was in progress.

Following a very excellent luncheon, the meeting was called to order by the president, Dr. Ralph M. Chambers. Election of officers being in order, the following were selected for the new year:

President: Dr. Arthur E. Pattrell, Boston Psychopathic Hospital. Vice-President: Dr. Roderick P. Dexter, Taunton State Hospital. Secretary-Treasurer: Dr. N. A. Dayton, Wrentham State School.

In opening the program, the Assistant Superintendent, Dr. E. C. Noble, sketched the development of Occupational Therapy at the Boston State Hospital over a period of years. In so doing, he stressed the importance of an agreeable personality in the workers in this department. Too often Dr. Noble has seen highly trained workers prove complete failures simply because they were unable to gain the confidence of their patients sufficiently to stimulate their interest. Once the importance of this factor was recognized and the need supplied, the department of Occupational Therapy developed at a rate formerly thought impossible.

Dr. E. W. Pease presented a paper dealing with recoveries and remissions in General Paralysis of the Insane without treatment. After summarizing the literature of this particular phase of the disorder, he presented a case with several very interesting features. A man of 41 was admitted with all the classical symptoms of a mentally unbalanced parietic, including positive blood and spinal fluid. A few months after admission, he had a very severe streptococcus infection of one foot. While recovering from this, he began to show gradual improvement in both psychical and physical spheres. The patient became much quieter, judgment and thought processes were improved, and he developed insight. Greatly increased interest in environment and an eighteen-pound gain in weight were observed. Neurological findings remained unchanged. Steady improvement over a two-year period resulted in the man leaving the hospital and obtaining work as a janitor, in which occupation he has remained for the past eight years. When the patient left the hospital, his blood and spinal fluid were negative, the cell count and gold curve presenting only slight deviation from normal. Discussion by Drs. Hanson, Noble, Chambers, Overholser and Pease.

An unusual case of Traumatic Psychosis with Epilepsy was presented by Dr. R. B. Dexter. At the age of forty-three the patient met with an accident, fracturing skull in the upper frontal region. Decompression revealed injury of both tables of skull and the brain lacerated and dirty. Over the following two years the patient showed gradual mental deterioration, being obliged to accept lower positions and finally being discharged. With negative family

and personal histories epilepsy developed at fifty-three, or ten years after the primary injury, and within a short period the attacks were very typically those of grand mal. Seventeen years after injury, or at the age of sixty, the psychosis appeared, somatic delusions and varied persecutory ideas holding the foreground. Following admission for the mental disturbance, roentgenograms showed erosion at seat of injury and a second operation was done by Dr. Irving P. Walker. The patient was greatly improved for three months, but at the end of that time the seizures and psychotic episodes reappeared, and have continued up to the present. Discussion by Drs. Wood, Noble and Dexter. Meeting adjourned.

NEIL A. DAYTON, M.D., *Secretary*.
Wrentham State School.

TRIBUTE TO MRS. ELIZABETH J. COLLINS.

BY JOHN W. FARLOW, LIBRARIAN, BOSTON MEDICAL LIBRARY.

At a meeting of the Executive Committee of the Boston Medical Library on October 16, 1922, the following resolutions were passed:

"In the death of Mrs. Elizabeth J. Collins, the Library loses its faithful Cataloguer for forty-two years. Her untiring devotion to the cause of medical literature, with its difficult questions of classification and cataloguing, has been of the greatest value to the medical profession; and the Executive Committee wishes to record its appreciation of the important part that she took in the growth of the Library from its small beginnings in 1880 to its present influence in the community."

Mrs. Collins was born in Boston, October 16, 1850, and died there September 1, 1922. She was obliged to leave school at the age of fourteen, on account of the death of her father. A year later, she obtained a position in the Boston Public Library, where she remained until her marriage to Mr. Thomas Collins in 1876, returning to the library after his death in 1879.

She received a thorough training under Mr. Justin Winsor the librarian, who assigned to her the task of looking after the medical section, especially the books received from the Massachusetts Medical Society in 1873. The proper methods of classifying medical literature were little understood until the publication of the Index Medicus and the Index Catalogue of the Surgeon-General's Library under the direction of Dr. J. S. Billings in 1880. The knowledge of medical periodicals, especially the American, was very limited, and Mrs. Collins, a pioneer in Boston in medical cataloguing, had little to guide her up to that time. Fortunately, she saw more or less of Dr. J. R. Chadwick,

librarian of the recently started Boston Medical Library, who came to the Public Library to talk with Mr. Winsor and, incidentally, to try to get from him material for the young medical library. Seeing her keen interest in this work, and noting her great perseverance, Dr. Chadwick induced her to give part of her time to helping him at the Medical Library; and what was also most important, he induced Dr. Calvin Ellis to pay for her services, there being no money available in the treasury of the library. She gradually gave more and more time to helping Dr. Chadwick, and in 1881, when she was established at the Medical Library in a definite position as cataloguer, he referred to her as "specially qualified for her work by many years of similar service at the Public Library."

When she was in difficulty, she consulted Dr. Chadwick, and through him Dr. Billings. Although the first volume of the Index Catalogue came out in 1880, it was many years before the entire series was published. Through the friendship of Dr. Chadwick and Dr. Billings, it was often possible to receive advance information from Washington as to books and periodicals which had not yet been described in the Index Catalogue.

In 1906 the medical collections of the Public Library, about 11,000 in number, including those that came from the Massachusetts Medical Society in 1873, were deposited in the Medical Library, the very books that Mrs. Collins had worked over in the Public Library. The regular library hours were not long enough for her, and she generally carried home at night packages of cards, lists of books and references, over which she spent her evening hours in order to get on with her ever-expanding task. This assiduous work she continued for forty-two years, with an industry and conscientiousness that never flagged. Even in her last year or more of broken health she thought only of the library, and continued to the very end to give to it the best of which she was capable.

The Boston Medical Library and the medical profession owe her a debt of gratitude for her lifelong devotion to the best interests of medical literature.

Miscellany.

THE ANNUAL MEETING OF THE NATIONAL COMMITTEE FOR MENTAL HYGIENE, INC.

The 13th Annual Meeting and Luncheon of the National Committee for Mental Hygiene was held at the Pennsylvania Hotel in New York on November 9th. Addresses were made by Dr. Haven Emerson, Professor Stephen P. Duggan, Mr. John J. Carty of New York, Professor Elton Mayo of the University of

Queensland, Australia, and Dr. Frankwood E. Williams, Medical Director of the National Committee.

Dr. Emerson spoke on the importance of the mental hygiene movement as a public health factor and asked for the support of those who have hitherto subscribed to the movements against infant mortality, tuberculosis and the other infectious diseases. He also pleaded for the wider education of physicians in mental diseases, after showing that more lay people were acquainted with the subject than doctors.

Dr. Walter B. James of New York was re-elected President of the Committee. Other officers elected were Dr. Charles W. Eliot, Dr. Bernard Sachs, and Dr. William H. Welch, Vice-Presidents; Mr. Otto T. Barnard, Treasurer; and Mr. Clifford W. Beers, Secretary.

Among those re-elected to membership were: Dr. Lowellys F. Barker and Dr. J. M. T. Finney of Maryland; Dr. Frank Billings of Illinois; Dr. George W. Crile of Ohio; Dr. L. Emmet Holt, Dr. John H. Finley, Mr. John J. Carty and Judge Learned Hand of New York; and Dr. Harvey Cushing, Dean Roscoe Pound, Dr. Anson Phelps Stokes, Dr. Joel E. Goldthwait, Dr. Austen Fox Riggs, President William A. Neilson and Dr. Henry R. Stedman of Massachusetts. Among the new members elected were Dr. Frederick C. Shattuck and Hon. Herbert C. Parsons of Boston.

OBSERVANCE OF AMERICAN EDUCATION WEEK.

Two years ago Dr. P. P. Claxton, former Commissioner of Education, instituted the observance of the first week in December as "Education Week." The American Legion last year became interested in the perpetuation of such a week and took the initiative in inviting the National Education Association and other organizations to coöperate in the observance of "American Education Week." This year the United States Bureau of Education in coöperating with the American Legion and the National Education Association in inviting every American organization, club, church, school, newspaper, magazine, theatre and individual and bodies of every description to participate in making the week, December 3-9, a real nationwide revival of educational enthusiasm.

It seemed wise, in order that the campaign might be concentrated upon phases of education which are of outstanding significance, to designate certain days on which topics should be stressed. These days are as follows: Sunday, December 3, God and Country; Monday, December 4, American Citizenship; Tuesday, December 5, Patriotism; Wednesday, December 6, School and Teacher; Thursday, December 7, Illiteracy; Friday, December 8, Equality of

Opportunity; and Saturday, December 9, Physical Education and Hygiene.

The placing of Physical Education and Hygiene at the bottom of the list may not indicate a lack of appreciation of the importance of this department of education but the result may be that less interest will be created. "God and Country" and "American Citizenship" could have been combined in one exercise and Monday, Dec. 4, have been given to "Physical Education and Hygiene." The promotion of health and physical efficiency is a fundamental condition affecting a country's progress and should occupy a most prominent place in an educational program.

Correspondence.

LONDON LETTER

(From our own Correspondent)

London, Nov. 11, 1922.

THE RISE AND FALL OF SURGICAL OPERATIONS.—Mr. James Berry, the well known London surgeon, on the evening of Nov. 1, gave an address as President of the Section of Surgery of the Royal Society of Medicine, at the home of the Society, 1, Wimpole Street, London, W. Mr. Berry as a student witnessed the last of the pre-antiseptic days, and had watched the development, first of antiseptic surgery and later the gradual development of the aseptic régime, under which so many of the greatest advances of modern surgery have been made. In the eighties operative surgery of the skull and brain was in its infancy. Mr. Berry pointed out that now experience and skill were especially essential in brain surgery. An operation on the brain which might be a brilliant success in the hands of a Harvey Cushing or a Sergeant might prove a terrible disaster when performed by a man with inadequate skill or insufficient experience. It was a truism to state that most of the progress made in surgery was due to the application first of antiseptic and later of aseptic principles. He could recall the days when eminent surgeons operated in old frock coats, splashed with blood and besmeared with pus. Indeed the more dirty the coat, the greater seemed to be the pride of the surgeon who wore it. The surgeon of those times did not trouble to wash his hands before an operation and Mr. Berry has actually seen a surgeon bite a ligature. He emphasized the point that it is of equal importance to know when to operate and how to operate and in support of this statement quoted a saying of a very great French surgeon: "I can teach my assistants to operate in the space of six months, but it takes twenty years of experience to know when to operate."

Perhaps, however, the special features of the address were those parts dealing with the results of operations for appendicitis and the tendency brought about by the war, of inexperienced men operating for the relief of serious conditions. Mr. Berry's remarks on the surgery of appendicitis should be of particular interest to New England and Boston medical readers, on account of the fact that appendicitis was in a manner of speaking discovered in Boston. Fifteen years ago he had expressed the opinion in the *Lancet*, Sept. 7, 1907, that if we were to all go back to the old treatment of appendicitis that was in vogue 25, now 40 years ago, that there would be a lesser mortality than there is at present. Fifteen years of further experience had confirmed him in this view. Of course, he did not suggest that the experienced surgeon should not operate for acute appendi-

citis, or even that there were not many cases in which immediate operation was not necessary. But he did think that much more care should be taken in the selection of cases for operation as regards both time and manner. It was the common belief of the public and the profession that the custom of operating freely for acute appendicitis had resulted in a great saving of life. In that case deaths from appendicitis should be less common than they used to be, unless one held the view, as some boldly do, that appendicitis was a disease that was becoming increasingly frequent, and there was no clear evidence of this. Various tables, referring to appendicitis, gastric ulcer, intestinal obstruction and peritonitis, compiled from the Registrar General's returns for England and Wales, extending over a period of twenty years, were exhibited and these seemed to show, so far as statistics can show, that deaths from appendicitis have in fact increased. Mr. Berry admitted that figures were often misleading although he did not go so far as the late Professor Black of Glasgow, who said that "statistics," like sausages, "depended a good deal upon the old woman who made them." But he thought that the figures he exhibited, if they meant anything, tended, at least, to show that the mortality from appendicitis has not diminished since the custom of operating for acute appendicitis has been so widely prevalent.

Mr. Berry held that the war had advanced surgery in some respects but in others had exerted a harmful effect. Nowadays many dangerous operations were being undertaken by men whose qualifications consisted of a few years' practice in military surgery, but such surgery has rarely occurred in civil practice. He pointed out that this kind of limited experience by no means qualified a surgeon to operate for serious conditions which occurred in civilian surgery and which called for a considerable amount of skill and experience. But country practitioners in all parts of Great Britain felt themselves competent to operate in cases of this description. Seeing that a skilled and well trained surgeon was available in nearly every large town in Great Britain, Mr. Berry thought it obviously unwise for the medical practitioner without much experience to run the risk of undertaking extensive operations except in cases of great urgency. Mr. Berry's definition of a "good surgeon" is one who always knows when to put in and when to take out a drainage tube.

THE CAUSATION AND PATHOGENESIS OF RICKETS.—Another presidential address of exceptional interest which has been given recently in the building of the Royal Society of Medicine in London, was that of Dr. Eric Pritchard, as President of the Children's Section, on Oct. 27, last. Perhaps there is no disease which is giving rise to such diverse views among those who have made a special study of the subject, with regard to causation, treatment and so on, as rickets. Perhaps, the most prevalent view at the present time is that it is a condition brought about by faulty hygiene, a disease of environment in fact. In Great Britain, Professor Noel Paton and Dr. Leonard Findlay of Glasgow are the chief upholders of this theory. Not long ago, the view mainly held as to its causation was the deficiency of the fat-soluble A vitamin and it was almost classed with the deficiency diseases on that account. Dr. Eric Pritchard is of the eminently common-sense opinion that the condition is not due to one cause but to several. He said in his address that he had chosen the subject of rickets for two particular reasons. 1. He had devoted more attention to it than to any other in medicine. 2. He regarded it as the most widely spread disease in the whole domain of pediatrics. He pointed out that lack of sunshine and want of fat had long been recognized as causes of rickets, nor was the vitamin theory new except in name. It may be mentioned here that Dr. Pritchard has pub-

lished recently the fourth edition of his book, "The Physiological Feeding of Infants and Children" in which the question of rickets is dealt with at length. In his address he drew attention to the fact that all conditions of malnutrition in infants, bad nutrition, bad hygiene, etc., must lead to rickets, because they all conduce to the development of acidosis and consequently to mineral depletion and calcium impoverishment. Rickets is an outcome of acidosis. In all conditions leading to rickets there is an excessive production of acid bodies in the system; that these acid bodies must be found in excess if the amount of food exceeds the physiological requirements. According to Pritchard the more usual contributing etiological factors are: chronic infections, vitamin stagnation, such as fat, soluble A and anti-scurvitics, metabolic disturbances, endocrine defects, such as adrenal, thyroid and pituitary insufficiency depressants. It was further pointed out that calcium depletion had three very obvious defects: 1. want of mineralization of bone; 2. muscular weakness; 3. nervous irritability. The successful prophylactic treatment of rickets is the same as that of acidosis, and the curative treatment is identical. Dr. Pritchard in concluding laid stress on the point that there is no one cause of rickets, the causes are multiple.

SMALLPOX IN LONDON.—There is an outbreak of smallpox in London, although at present, at any rate, it is mainly confined to one district. The Ministry of Health urge emphatically the desirability of vaccination. Sir George Newman, the chief medical officer of the Ministry, said a short time ago that for the whole of England and Wales only 40 per cent. of the babies born are being vaccinated, and it is my duty to say quite explicitly that this condition of things brings with it, in greater or less degree, an increased risk of smallpox to the nation as a whole. It is satisfactory to state that there has been somewhat of a rush to be vaccinated. A rather interesting incident in connection with the outbreak is that a considerable amount of insurance has been placed at Lloyd's against the risk of contracting smallpox, policies paying a total loss in the event of the insured person contracting the disease. The rates demanded are one shilling (25 cents) per cent. if the insured person had been vaccinated within the past ten years, and two shillings (50 cents) per cent. otherwise. Representation in the Royal College of Surgeons.—At the forthcoming annual meeting of the Fellows and Members of the Royal College of Surgeons to be held on November 16, a resolution is to be proposed "again affirming the desirability of admitting members to direct representation on the Council of the College which, as now constituted, only represents those members who hold the Fellowship." The resolution adds that as the college is composed of about 18,000 persons, of whom 16,000 are engaged in general practice, "that the President and Council should nominate at least two members in general practice to represent the interests of general practitioners on the Council."

TOUR FOR MEMBERS ATTENDING THE ANNUAL MEETING OF THE A. M. A.

New York, Nov. 14, 1922.

Dr. W. L. Burrage, Secretary Massachusetts Medical Society, 42 Elliot Street, Jamaica Plain, Boston, Mass.

My dear Dr. Burrage:

We are planning a tour for the members of the Medical Society of the State of New York and their friends to the A. M. A. meeting next June in San Francisco.

Our President, Dr. Arthur W. Booth, has suggested that we place our plans in the hands of all the delegates to the A. M. A., and the State Secretaries from the Eastern States.

We will therefore appreciate your sending us the names and addresses of the County Secretaries and the delegates to the A. M. A. convention from your State Society, so we may be in a position to send them particulars regarding this trip.

Kindly give this as much publicity as possible among your friends.

We expect to give a better trip at lower cost than will be possible to those traveling alone.

Thanking you in anticipation of your complying with our request, we remain,

Yours truly,

MALCOLM C. ROSE, Chairman.

152 W. 42nd Street at Broadway, Times Square.

[NOTE.—Dr. Burrage has given the desired information.]

RECENT DEATHS.

DR. ALBERT HENRY BECK, who was clinical professor of diseases of the ear at the College of Physicians and Surgeons, New York, from 1888 to 1904, and for many years one of the leading aurists of the city, died November 16, 1922, in his eighty-first year at his home in Cornwall, N. Y. He graduated from Yale in 1864 and finished his medical education in Europe and at the College of Physicians and Surgeons at Columbia in 1867. He was editor of *Hygiene and Public Health* in 1879, founded and edited the first two editions of the Reference Handbook of the Medical Sciences, was co-editor of *American Practice of Surgery* and author of "Diseases of the Ear."

He is survived by a wife, formerly Laura S. Abbott, whom he married in 1871.

DR. WILBER PRAY SAFFORD died at Brockton, November 16, 1922, at the age of sixty-seven.

He was born in Boston, February 20, 1855, was graduated from Dartmouth Medical School in the class of 1892, studied medicine further in the New York University Medical College, and settled in New York City.

He came to Brockton and joined the Massachusetts Medical Society in 1904, conducting a private lynch-in hospital at No. 52 Pleasant Street. This building was recently taken by the city as the site for a fire apparatus station and the doctor was forced to move, against his wishes.

He is survived by his widow, a sister, and a nephew.

DR. GEORGE WILLIAM DOW, medical examiner of the 5th Essex District since 1900, died at his home in Lawrence of heart disease, November 21, 1922, at the age of 71. He was a member of the Staff of the Lawrence General Hospital and had been alderman and city physician. He was a Brown graduate (1877) and Harvard Medical (1881). He was M. M. S. His widow and a son survive him.

DR. FRANK HUNTER ZABRISKIE died at Groenfield, Oct. 23, 1922, aged 63. He was a member of the American Medical Association and of the Massachusetts Medical Society.

BOOKS RECEIVED FOR REVIEW.

The Journal acknowledges the receipt of the following books for review:—

De Arte Physicâ et de Chirurgia of Master John Arderne, Surgeon of Newark, Dated 1412. By SIR D'ARCY POWER. Published by William Wood & Co., New York. 60 pages. Price \$4.

NEW ENGLAND DERMATOLOGICAL SOCIETY.

The regular quarterly meeting of the New England Dermatological Society will be held at the Boston City Hospital, in the Surgical Amphitheatre, on De-

ember 13, 1922, at three thirty p.m. All physicians who are interested are invited to attend.

SPECIAL MEETING TO DEMONSTRATE THE SCHICK TEST.

All physicians doubtless know something about the Schick test, but do they know enough? The value of the test in practice depends upon its application in the right way and above all on correct reading of the results. It is necessary to distinguish four kinds of results: namely, the negative reaction, the simple positive reaction, the pseudo-reaction, and the positive combined reaction, which is a combination of pseudo and positive reactions. To learn to differentiate these reactions is relatively easy when typical examples of each have once been seen.

The Norfolk District Medical Society recently held a special meeting at which demonstrations of the test were given and the meeting was well attended. The Suffolk District Medical Society now plans to hold a similar special meeting on December 5th.

At this meeting specially qualified speakers will discuss briefly the public health aspect, the practitioner's viewpoint, and the immunological principles of the test.

The technique of performing the test will be demonstrated and the various kinds of reactions will be illustrated by actual cases. Physicians who have not yet familiarized themselves with these matters will, it is hoped, take this opportunity so to do. Even though they might not contemplate performing the test themselves, they would then be better prepared to second the health authorities in their efforts to eliminate diphtheria.

THE WORCESTER DISTRICT MEDICAL SOCIETY.

Dr. A. Wilson Atwood has issued the following tentative programme for the rest of the year:

December 13, 1922—The meeting will be held in the G. A. R. Hall, Pearl Street. Programme: "Prostatectomy," Dr. J. D. Barney of Boston; "Anomalies of the Kidney," Dr. Walter D. Bieberback; "A Series of Interesting Pyelograms in Genito-Urinary Lesions," Dr. Philip H. Cook.

January 10, 1923—The meeting will be held at the Worcester State Hospital, Belmont Street, at 4.15 P. M. Programme: "A Discussion of Status Thymico-Lymphaticus and the Inherent Compensatory Possibilities," Dr. Walter Timme, New York City. Discussion will be opened by Dr. W. A. Bryan.

February 11, 1923—The meeting will be held at the Worcester City Hospital at 4.15 P. M. The programme will consist of a series of papers by members of the staff.

March 11, 1923. The meeting will be held at St. Vincent's Hospital at 8.15 P. M. The programme will consist of a series of papers by members of the staff.

April 11, 1923. The meeting will be held at Memorial Hospital at 8.15 P. M. and the programme will consist of a series of papers by members of the staff.

May 9, 1923. Annual meeting and banquet.

Approximately 75 patients visited the special cancer clinics at the Worcester hospitals as the result of the publicity given to the matter by the last public meeting of the Society and the splendid work of the press.

SOCIETY MEETINGS.

DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue.

Barnstable District:—Hyannis,—February 2, 1923, (Annual Meeting)—May 4, 1923.

Bristol South District:—Fall River,—May 3, 1923.

Essex North District:—Haverhill, (Semi-Annual Meeting)—January 3, 1923. Y. M. C. A. Building, Lawrence, (Annual Meeting)—May 2, 1923.

Essex South District Medical Society meets Wednesday, December 13th, at Beverly Hospital, Beverly, 6 P. M. Speakers: Dr. W. P. Bowers, Managing Editor *Boston Medical and Surgical Journal*; Dr. John D. Adams, Boston; Dr. P. F. Johnson, Beverly. R. E. Stone, Secretary.

Suffolk District:—December 27, 1922; January 31, 1923; February 28, 1923; March 28, 1923; Annual Meeting, April 25, 1923.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexis Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, Hist. The date for each speaker has not been assigned.

Middlesex North District:—Meeting, Wednesday, January 31, 1923.

Middlesex East District:—Jan. 24, 1923. The Nursing Problem. Speaker to be announced later.

March 21, 1923. Mental Factors in Childhood. Paper by Dr. William Healy.

April 18, 1923. Interpretation of Laboratory Findings. Papers by Dr. E. G. Crabtree and one to be announced later.

May 9, 1923. Annual Meeting.

All meetings except the annual meeting will be held at the Harvard Club in Boston. A. E. Small, Secretary.

Worcester District meetings in Worcester, Dec. 13, 1922, Jan. 10, Feb. 14, March 14, April 17 and May 9, 1923, the last named date being the annual meeting.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

December, 1922.—New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 3.30 P. M., in the Surgical Amphitheatre, Boston City Hospital; C. Guy Lane, Secretary.

December 26-30, 1922:—American Association for Advancement of Science meets in Boston.

December, 1922.—Boston Medical History Club will meet December 18, 1922.

January, 1923.—Massachusetts Society of Examining Physicians (date and place undecided); Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston; W. H. Allen, Mansfield, Mass., Secretary.

January, 1923.—Boston Association of Cardiac Clinics. Meeting January 18, 1923, at 8.15 P. M. Boston Lying-In Hospital (New Hospital). Subject: Pregnancy and Heart Disease.

January, 1923.—Boston Medical History Club will meet January 15, 1923.

February, 1923.—New England Dermatological Society Meeting, February 14, 1923, at 3.30 P. M., in the Skin Out-Patient Department, Massachusetts General Hospital; C. Guy Lane, Secretary.

February, 1923.—Boston Medical History Club will meet the third Monday of this month.

March, 1923.—Massachusetts Society of Examining Physicians (date and place undecided); Hilbert F. Day, Secretary.

March, 1923.—Boston Association of Cardiac Clinics. Meeting March 15, 1923, at 8.15 P. M. Boston City Hospital. Subject: Prevention and Relief of Heart Failure.

March, 1923.—Boston Medical History Club will meet the third Monday of this month.

April, 1923.—New England Dermatological Society Meeting, April 11, 1923, at 3.30 P. M., in the Surgical Amphitheatre, Boston City Hospital; C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston; W. H. Allen, Mansfield, Mass., Secretary.

April, 1923.—Boston Medical History Club will meet the third Monday of this month.

May, 1923.—Massachusetts Society of Examining Physicians (date and place undecided). American Pediatric Society Meeting, May 31, June 1 and 2, 1923, at French Lick Springs Hotel, French Lick, Ind.; H. C. Carpenter, Secretary.

May, 1923.—Boston Association of Cardiac Clinics. Meeting May 17, 1923, at 8.15 P. M. Children's Hospital. Subject: Rheumatism and Heart Disease.

June, 1923.—American Medical Association, San Francisco, June 25-29, 1923; Alexander R. Craig, Chicago, Ill., Secretary.

July, 1923.—Massachusetts Association of Boards of Health, July 26, Nantasket; W. H. Allen, Mansfield, Mass., Secretary.

*Decreased September 2, 1922.

THE WASSERMANN TEST.

I. WASSERMANN TESTS IN A BOSTON MATERNITY HOSPITAL.

BY DAVID L. BELDING, M.D., BOSTON, AND
CHARLOTTE B. ADAMS, BOSTON.

[From the Evans Memorial.]

WASSERMANN surveys upon hospital or dispensary patients who suffer from various pathological conditions including syphilis, do not represent the normal incidence of syphilis or the true per cent. of positives among the so-called healthy population. Theoretically, maternity cases which present a physiological rather than a pathological condition, more closely approximate the normal. Practically, changes in the blood of the pregnant woman so affect the test that maternity patients are no more representative than ordinary hospital cases. In spite of this fact and with the additional knowledge that statistical deductions from small groups are more or less untrustworthy, it seems fitting to present a series of 5198 maternity cases on whom routine Wassermann tests were made at the Robinson Memorial, Massachusetts Homeopathic Hospital, Boston, in the hope that it may add to the rapidly accumulating mass of evidence regarding the extent of syphilis among various classes of society. It is also of interest, in that

it touches directly upon the great question of congenital syphilis.

Syphilis and the Wassermann Test.—It is a matter of common knowledge that the Wassermann test, based on a non-specific fixation, does not detect all cases of syphilis. Negative tests are frequently obtained in syphilitics, particularly in old or treated cases, and infrequently positive reactions are obtained in other diseases. Therefore, a Wassermann survey, although the most reliable method at our command for determining the existence of syphilis, does not represent the actual extent of the disease in a community, and the incidence thus determined must be interpreted from the standpoint of positive Wassermann tests rather than the number of syphilitics.

It should be clearly understood that the statistics in this paper are the results of a Wassermann survey among pregnant women and do not represent the actual incidence of syphilis in greater and suburban Boston. Neither are they comparable with a Wassermann survey of a similar body of non-pregnant women, owing to certain technical variations in the reaction due to pregnancy, upon which preliminary studies are now under way.

In latent or hidden syphilis, the type ordinarily found in maternity cases, Craig¹ found that 32 per cent. gave a negative Wassermann test. Thus a Wassermann survey underestimates the number of cases which have had or still have clinical syphilis. Ordinarily with cholesterolized

antigens, comparatively few non-syphilitic fixations are obtained; but in maternity cases this number is increased, approximately ten times, while the number of syphilis with negative tests remains unchanged. Curiously, these errors so balance in maternity cases that the per cent. of positives approximates the actual number of syphilis in a community, even though all cases of syphilis are not detected and a corresponding number of non-syphilis is included.

Technique.—In all studies regarding the prevalence of syphilis by means of the Wassermann test, the method of performing the test and the type of antigen should be carefully recorded. Otherwise subsequent comparisons are impossible owing to technical differences in determining what constitutes a positive Wassermann.

During 1917 and 1918, 2470 routine cases were run with a special technique in which a cholesterolized and an acetone insoluble antigen were used. During 1919 and 1920, 2728 cases were tested by the standard method of the Massachusetts Department of Public Health with two cholesterolized antigens. (Hinton.²) Our statistics, unless otherwise specified, are based upon a 0.4 per cent. cholesterolized beef heart antigen, which was used throughout both series. The close results with the same antigen, the per cent. of positives being 9.1 for Series I and 9.3 per cent. for Series II, suggest that the actual technique of performing the test is perhaps less important than the type of antigen and the method of reporting.

The two methods which are compared in Table No. 2, differed chiefly in regard to the total volume, preliminary titration of serum and method of reporting, although based upon the same hemolytic system and upon similar principles. In Series II the standard method of the Massachusetts Department of Public Health was followed, except in the number of antigens and the method of reporting. Whereas in the State Wassermann Laboratory three cholesterolized antigens are employed and the results are reported as positive when all three give complete or moderate inhibition, doubtful when antigens A and B show 75 per cent. hemolysis, with slight or no hemolysis with C, and negative when all three give complete hemolysis; in Series II, two cholesterolized antigens, one of which for a short period was replaced by a plain alcoholic, were used and the positives were graded according to the time-honored but unsatisfactory 1 to 4 plus system.

The particular cholesterolized antigen upon which the statistics are based, through the courtesy of Dr. W. H. Hinton of the Wassermann Laboratory, Massachusetts Department of Public Health, has been compared with the standard State antigen on 108 questionably syphilitic cases. Agreement resulted in 95 cases while the State antigen proved stronger in 4 and weaker in 9. In 78 cases, positive with one or

both antigens and also positive with a third, the State standard was positive in 96.1 per cent. and our antigen in 97.4 per cent. Except for an occasional weaker reaction with one or the other, the two antigens may be considered practically of equal strength and value.

TABLE NO. 1.

<i>Antigen.</i>						
Standard Cholesterolized Antigen of Massachusetts	Cholesterolized Antigen No. 1.					
		Positive.	Moderate Positive.	Weak Positive.	Negative.	Total.
	Positive	57	2	—	—	59
	Moderate Positive	2	1	—	—	3
	Weak Positive	1	3	7	2	13
	Negative	—	—	3	30	33
	Total	60	6	10	32	108

Eighty-seven per cent. of the laboratory work was performed by the same technician, thus largely eliminating the personal equation. The blood was taken in the prenatal clinic and in the delivery room. Tests were run twice a week in Series I, and three times in Series II.

Results.—Positive reactions of varying degrees were obtained in 9.2 per cent. of cases, of which 7.8 per cent. would have been reported as positive in laboratories where doubtful reactions (1-plus) were disregarded, and 4.6 per cent. were strongly positive. The total number of negroes, 3.5 per cent. of all patients, is too small to cause any appreciable change in the per cent. of positives. The minor differences between the two series in Table No. 3, is largely due to the different method of reporting, an eight-point system being used in Series I and a four-point system in Series II.

Clinical Syphilis.—The positive cases have been classified clinically as (A) *Definitely Syphilitic*, when there is no possible doubt as to the clinical diagnosis; (B) *Suspicious*, when there are several suggestive symptoms but the evidence is not conclusive; (C) *Suggestive*, when a single symptom or sign suggestive of the disease is present; and (D) *No Indication*, when no clinical evidence can be obtained. The statistics are given on a basis of 4988 cases rather than the original 5198, owing to the fact that in Series I only 207 of the 224 positive cases examined in the prenatal clinic entered the hospital for delivery. They are arranged according to the inclusion or exclusion of the findings in the child of the present pregnancy. In general "Exclusive Child" refers to the clinical evidence available at the prenatal clinic and "Inclusive Child" includes the total clinical evidence at the time the patient leaves the hospital.

The small percentage of cases which give clinical evidence of syphilis is in accord with the findings of most investigators of syphilis in

D. No indications	64.2	58.3	60.9	52.6	39.0	45.1

women. Since these cases chiefly represent "hidden" syphilis, it is difficult to obtain clinical evidence of the disease even by most careful questioning as to history, children, symptoms, fetal deaths, etc. As a rule the patients have no knowledge of, or show no signs of syphilitic infection. With all available information only 9.8 per cent. can be classed as definitely syphilitic and 19.9 per cent. more as probably syphilitic, while at the prenatal clinic these figures fall to 5.8 and 11.7. It is indeed a marked contrast to syphilis in the male that less than 10 per cent. of females give definite clinical findings, less than 20 per cent. more present suspicious symptoms or histories, and 45 per cent. give no indication whatever. For reasons previously stated concerning the Wassermann test in pregnant women and the probable inclusion of non-syphilitics, the 10 per cent. represents a minimum figure.

The variation between the two series in the per cent. of definite and suspicious syphilis, demonstrates the need of using large numbers of cases in the compilation of medical statistics.

Comparative Statistics.—The results of routine Wassermann tests upon pregnant women in nine other cities have been collected from the literature. With one exception only cities reporting five hundred or more cases have been included. While the average of 9.03 per cent. for 16,639 cases is practically the same as 9.2 per cent. for Boston, it would fall considerably below this figure if the large number of negroes in Baltimore (50 per cent.) and in Washington (77 per cent.) were eliminated. It would seem that our 7.8 per cent. for reportable positives (eliminating the doubtful 1-plus reactions), closely approximates the general incidence of positive Wassermanns in this class of patients.

TABLE NO. 5.
Comparison of Cities.

Cities.	Total Cases.	Per Cent. Positive.
Ann Arbor—3, 4.....	1,024	5.8
Baltimore—5.....	4,000	11.2

Minneapolis—12.....	857	6.2
New York—13, 14, 15.....	4,882	8.0
Paris—16.....	1,185	4.4
Washington—17.....	863	27.8
Total.....	16,639	9.03

Comparisons of this kind, even with comparatively large numbers, are of little value, owing to different methods of performing the test and variations in the source of material. For this reason all Wassermann statistics should be accompanied by the method of performing the test and a description of the subjects and their environment. In order to show the necessity of recording certain information relative to the patients, and for the purpose of presenting our

statistics for future comparisons, the influence of the following conditions is considered: I. Individual Variation, (1) Age, (2) Time married. II. Nationality. III. Social and Economic Position, (1) Wealth, (2) Occupation of husband, (3) Residence.

Individual Variation.—An accurate comparison of syphilis in women cannot be made unless groups of approximately the same age and length of married life are selected. For this reason the excellent records for Boston of Solomon and Solomon,¹⁸ upon women averaging 37 years old and married 11.09 years, which were selected from the standpoint of neurosyphilis, cannot be compared with the present series of younger women. Presumably since a large per cent. of syphilis in women is acquired through the husband, the older the patient and the longer the period of married life, the greater becomes the opportunity for infection.

(1) *Age.*—The distribution according to age, as shown in Table No. 6, indicates that nearly 80 per cent. of the patients at the Robinson Memorial Hospital were comparatively young women under 30 years. The average age of 461 positive cases was 26.52 years and of 500 negative 26.16.

TABLE NO. 6.

Age.	Distribution per 1000.	Per Cent. Positive.		Total.
		Series I.	Series II.	
15-20 years	136	8.8	8.6	8.7
21-25 " "	386	9.6	8.8	9.2
26-30 " "	271	8.1	9.4	8.8
31-35 " "	129	7.7	9.5	8.7
36-40 " "	64	11.3	11.3	11.3
41-45 " "	13	19.4	14.7	16.9
46-50 " "	1	0.0	33.3	14.3

If active syphilis were under consideration certain ages would probably show an increased number of positives, but since the Wassermann test includes all stages of the disease we should expect, in view of the longer period of exposure, a greater per cent. with advancing years, particularly if we assume that increased age is comparable to longer married life. The smaller number of cases above 35 years in some measure accounts for the unusually high per cent., but 00 cases are at least sufficient to warrant the conclusion that the older women show an appreciable increase in the number of positives.

Series II gives a steady rise with increasing age, but Series I shows an unexpectedly high rate in the 21-25-year group. Naturally we should expect to find a greater number of active syphilis during this period, which corresponds to the first years of married life, but more probably it denotes statistical error due to insufficient data.

(2) *Time Married.*—Comparing 461 positive cases with 500 negative, comprising the same nationalities, the negative series shows a greater number of primipare, 44.6 per cent. vs. 38.6 per

cent., and correspondingly a shorter average period of married life, approximately 2 months. In these cases the average number of conceptions was 2.46 for the positives and 2.22 for the negatives, which indicates that in fertile women syphilis has no influence on the number of conceptions. The greater number of multiparæ and the longer period of married life in the positive series, show that the latter exerts some degree of influence upon the percentage of positives. However, these figures are merely suggestive, since it is assumed that the two groups of 500 and 461 represent the correct average for all negative and positive cases.

Nationality and Race.—The influence of race and nationality, particularly in the case of the negro, is of sufficient importance to demand separate consideration, and for that reason only a single table for the purpose of interpreting our statistics is presented here. Except in the case of the Negro and the Jew the nationality is determined by the birthplace of the patient.

TABLE NO. 7.
Race and Nationality.

Nationality.	Distribution per 1000.	Per Cent. Positive.
Negro	35.2	17.1
Greek	7.4	16.2
Armenian	9.2	13.0
Scotch	12.0	10.0
American	553.1	9.4
French	2.2	9.1
Roumanian	2.2	9.1
Canadian	96.9	8.9
Irish	79.9	8.8
Germanic	10.2	7.8
Jewish	112.2	7.4
Scandinavian	16.6	7.2
British	35.9	6.7
Slavic	4.6	4.4
Turkish	6.2	3.2
Italian	10.6	1.9
Miscellaneous (11 nations)....	5.6	17.9

Social and Economic Position.—The social and economic status of the patient may be shown indirectly by the financial condition, the occupation of the husband and the residence. Owing to local interest, special attention is given the distribution of cases in greater and suburban Boston.

(1). **Wealth.**—The price paid for hospital accommodations, while not an absolute indication of the financial condition, nevertheless gives a fairly representative idea of the resources of the patient. The patients may be grouped into three main classes, according to the hospital charges effective in 1917.

TABLE NO. 8.
Financial Status.

Weekly Hospital Rate.	Distribu- tion per 1000.	Negro and White.	Per Cent. Positive.
Free and Reduced	99	11.1	10.7
\$12.00 to \$15.00	742	9.1	8.7
\$17.00 to \$21.00	159	8.6	8.6

There is but little difference between the grades of paying patients, but a decided difference, 2 per cent., between the semi-charity cases and the independent cases. The elimination of the negro causes practically no change in this situation, and the conclusion may be drawn that the prevalence of syphilis in some measure depends upon the financial status of the patient.

(2). **Occupation.**—Classification of the husband's occupation presents rather surprising results. Indoor occupation ranges higher than outdoor, clerical work giving the highest percentage, 15.1. Unskilled labor gives 11.4 per cent., as compared with 8.6 per cent. for skilled. Mechanical and manufacturing, 8.6 per cent., and public service, 7.8 per cent. are below the average, and unmarried women, although few in number, have an unexpectedly low rate, 4.8 per cent. Evidently the percentage of syphilis varies in different occupations, but in general it follows their economic status. These figures again emphasize the necessity of care in comparing statistics regarding the prevalence of syphilis.

TABLE NO. 9.

Occupation.

Occupation.	Distribu- tion per 1000.	Negro and White.	Per Cent. Positive. White.
Agriculture, Forestry and Fisheseries	11	8.9	8.9
Clerical	45	15.1	14.8
Domestic and Personal.....	64	9.4	9.5
Manufacturing and Mechanical	445	8.6	8.3
Professional	30	10.7	10.0
Public Service.....	72	7.8	7.9
Trade	160	9.5	9.6
Transportation	143	10.2	9.2
Unmarried Women.....	25	4.8	4.4
Not given.....	4	5.0	5.0
No occupation.....	1	0.0	0.0

(3). **Residence.**—Ordinarily the residence of the patient has little direct bearing upon her economic or social condition, owing to the mixed residential character of each community. Except in a few cases it would be manifestly inaccurate to draw conclusions in comparing one community with another, unless the general social status was markedly different. Likewise, comparisons to be accurate should be based on large numbers which are not available for the individual suburban towns. However, statistics showing the per cent. of positive Wassermann tests in different parts of suburban Boston are perhaps of local interest and may be presented here with the provision that no unwarranted conclusions be drawn. The figures for other cities (Table No. 6), while of interest as statistical compilations of various institutions, with the exception of New York, scarcely warrant comparison with Boston, which is a port of embarkation and debarkation in close touch with foreign shores and possessing a comparatively large mixture of foreign-born population.

TABLE NO. 10.
Zone Distribution.

Residence.	Distribution per 1000.	Per Cent. Positive.			
		All Degrees.		Strong.	
		Negro and White.	White.	Negro and White.	White.
Boston, Central District.....	221	10.8	10.2	5.7	5.4
Boston, excluding Central District.....	447	9.2	9.2	4.6	4.6
Suburbs within eight-mile radius.....	277	8.5	7.8	3.8	3.5
Outside Suburban Boston.....	55	6.6	6.7	4.8	4.8
Greater Boston.....	668	9.8	9.6	5.0	4.9
Boston and Suburbs within eight miles.....	945	9.4	9.0	4.6	4.5
Boston and Suburbs, excluding the Central District.....	724	8.9	8.7	4.3	4.2
All localities.....	1000	9.2	8.9	4.6	4.5

Ninety-four and one-half per cent. of all house cases admitted to the Robinson Memorial Hospital from 1917 to 1920, inclusive, came from Boston or suburbs within an eight-mile radius, so that for all practical purposes the entire series may be considered as coming from one locality.*

Greater Boston	66.8%
Suburbs within 8 miles	27.7
Massachusetts	4.7
United States	0.7
Canada and Mexico	0.1
	100.0%

(a) *City vs. Suburbs.*—The striking fact in the residential distribution of syphilis is the higher urban rate.* Irrespective of groupings, the central district of Boston, comprising the North, South and West Ends, always gives the highest per cent. Greater Boston exceeds the surrounding suburbs, and they in turn the rest

of Massachusetts. These facts cannot be explained from the standpoint of nationality or race, since the exclusion of the negro, the only appreciable factor, does not materially affect the per cent. of positives. On the basis of the cost of hospital room, the central Boston patients are upon the same financial level as the greater Boston and suburban for both positive and negative cases, and the semi-charity cases, which had the highest per cent. of positives, are equally distributed. No other explanation seems tenable except that syphilis is more prevalent in central Boston among the women who enter the hospital as house cases, than in the same economic class of patients from the suburban districts.

(b) *Suburban Distribution.*—Further information may be gained by arranging the residential districts and suburbs of Boston into geographical groups.* In so doing, however, the decreased number of cases makes the results of relatively less value.

(c) *Social Status.*—If we divide the thirty cities and towns into four classes, according to the social standing of the population, a corresponding difference is found in the percentage of positives. Naturally, this arbitrary division is somewhat dependent upon the person making the classification, since cities and even towns contain several social strata, but all observers would agree upon the difference between the highest and lowest class. In order to eliminate all possible error, only the white race has been considered. The results indicate that the social and intellectual standing of a community is

closely associated with the prevalence of syphilis.

The various communities which have furnished at least 100 patients may be arranged according to the per cent. of positives, but it should be remembered that statistics from small groups are unreliable.

SUMMARY.

1. In 5198 routine cases in a Boston Maternity Hospital, the Wassermann test showed some degree of positivity in 9.2 per cent., was definitely positive in 7.8 and strongly positive in 4.6.

2. Only 9.8 per cent. of the positive cases gave definite clinical evidence of syphilis, although an additional 19.9 showed suspicious findings.

3. Positive Wassermann tests, with cholesteralized antigens, in pregnant women are not comparable to similar tests in non-pregnant, owing to certain blood changes, and therefore do not either represent the actual incidence of syphilis in a community or the per cent. of positive tests in healthy non-pregnant women.

4. Statistical studies from various cities cannot be accurately compared, owing to differences in technique and material. For reference all Wassermann surveys should be accompanied by a statement of the method of performing the test and a description of the status of the patient.

5. Owing to longer exposure, the per cent. of positives increases with age and length of married life.

6. The high incidence of syphilis in the negro, twice that in the white race, necessitates the exclusion of this race in certain statistical comparisons. The prevalence of syphilis varies with different nationalities.

7. The per cent. of positives increases inversely as the wealth of the patient, and also differs according to occupation.

8. In Boston the urban rate is higher than the suburban and the highest class residential districts show the lowest per cent. of positives,

which, in this instance, explains the lower suburban rate.

CHANGES THAT HAVE OCCURRED IN THE PAST 25 YEARS HAVING AN EFFECT ON THE PROGRESS OF MEDICINE.*

BY ARTHUR W. MARSH, M.D., WORCESTER, MASS.

TWENTY-FIVE years ago last October, fresh from school and hospital, I came to Worcester and, to use the popular phrase, "hung out my shingle." During this period many changes have occurred in our ideas about some diseases and in the manner of treating many, and it has seemed to me that it might be interesting to review some of these changes and possibly prophesy some into the future. Influences within, as well as without the profession, have worked to bring medicine to its present standard, and will, in the future, exert, more than ever, an unavoidable effect on our work and our ideals.

To begin with, let me recite some of the conditions under which I was educated, and the views held at that time about some of the common diseases. In doing this I shall have to apologize for being personal somewhat, and for citing facts and incidents confined to this particular region, but I have no doubt that what I have to say, by merely changing names and things peculiar to any locality, could apply to a practitioner in any other section of the country.

Twenty-five years ago the Harvard Medical School occupied the one building on the corner of Boylston and Exeter Streets. The class that I was enrolled in was the last class to go through on the three-year schedule. A college degree was not required as an entrance qualification. The faculty included such men as E. M. Wood in chemistry, Thomas Dwight in anatomy. Councilman began his first year in the chair of pathology with my class. F. C. Shattuck and Mason headed the list in clinical medicine, and R. H. Fitz had just been transferred to the chair of theory and practice. David Cheever had just resigned the chair of surgery and J. Collins Warren had taken his place. Maurice

*Read before the Worcester District Medical Society, at Clinton, May 10, 1922.

Richardson was Professor of Clinical Surgery. William Richardson was Professor of Obstetrics, and Thomas Retch, Professor of Children's Diseases. All these men held prominent positions in the various hospitals.

The Massachusetts General and the Boston City were the two leading hospitals where we went for clinical teaching. At that time the number of internships in the various hospitals was such that, I venture to say, not more than one-half of each graduating class could be given the opportunity for hospital work. Today the Medical School is in its present palatial quarters and is surrounded by a new group of hospitals which, with the older hospitals, gives it a capacity for teaching hardly realized twenty-five years ago. The number of internes in all these institutions has been so largely increased that opportunity is given to nearly every student to round off his education by hospital training.

Outside of Boston the Worcester City Hospital was then looked upon as one of the most attractive, two of my own classmates coming up here for their hospital training. In Worcester itself there were four general hospitals. The City, which then consisted of K, F, G and M, with C and D and the Winslow Surgery as very recent additions. The out-patient was confined to the two or three small rooms in the basement of the Administration Building. The Memorial Hospital was then confined to the present Administration Building and the building next to it, now C and M, I believe, and the out-patient Washburn Free Dispensary. St. Vincent's was in the old wooden building at the junction of Vernon and Winthrop Streets, and the Hahnemann in an old wooden building half-way up the hill on Providence Street. The Isolation Hospital was completed and occupied either the year I came here or the year following. None of these hospitals had laboratories as we regard laboratories today.

During this twenty-five-year period all these hospitals have expanded until now the City has a capacity of more than 300 beds, with more than 50 rooms for private patients. The Memorial has 150 or more with a still greater proportionate increase in private rooms. The St. Vincent's and Hahnemann occupy new buildings with their capacity doubled or trebled. The Isolation has been added to and now includes under its management the Putnam Ward for the care of the City's tubercular patients. Those hospitals that maintained out-patient departments have seen their work expand until new buildings have been occupied and new departments added, while the laboratory has become an indispensable part of the equipment.

In the smaller cities and towns in the district which this Society represents, hospitals have and still are being organized. As I have said this picture is only a regional one, and by the substitution of other names, could be applied

to any other region in the neighborhood of our large cities throughout the country.

It means that medical education has developed and become more thorough. The student is more carefully trained in history-taking and the use of apparatus in making a diagnosis. It also means that the confidence of the public in hospitals has grown so that now not only the poor, but those who have good, comfortable homes, often prefer to go to a hospital for treatment. Especially is this so in surgery, since it is rather unusual to hear of an operation being done in a private house.

The views held of certain diseases in my student days are well worth comparing with the views we take of those same diseases today.

It was only five years before my going to the medical school that Fitz had demonstrated to the world the rôle played by the appendix in peritoneal inflammations. The treatment of appendicitis was not then so thoroughly regarded as surgical as now. The medical side of a hospital rather enjoyed twitting the surgical side over the fact that it could show a lower mortality rate for this disease than the surgical. It hardly needs an explanation for this.

I well remember a certain day at the Massachusetts Hospital, where we were attending a clinic conducted by Dr. Warren, when an emergency case of appendicitis came in. Dr. Warren, thinking it a good opportunity to demonstrate the value of a consultation before us, called in Drs. Fitz, Shattuck, Eliot and Porter, each of whom gave his opinion of the case and his treatment of it. The consensus of opinion was that it was a favorable case for operation. Today there would be no discussion on that point. A majority of cases seen in the hospitals then were the advanced cases and it was comparatively rare to see a clean case operated upon.

But at that time there were men, among whom I especially recall Dr. Worcester of Waltham, who were urging operation as soon as the diagnosis had been made, and we know their position has prevailed until not only the profession but the general public is alive to the value of early operation in this disease.

The correctness of this position is shown in a comparison of the statistics of the mortality rate between the past and the present. Malaria was, or seemed to be, more prevalent then than now, and various ideas were advanced as to its etiology—the old miasma theory was hardly dead. Around Boston, residence along the banks of the Charles or the Mystic River, was supposed to render people more liable to it. The relation of the mosquito to the spread of the disease was demonstrated later.

There was much discussion in those days, and we were often called on to explain the difference between contagion and infection to inquisitive patients, and were sometimes hard put to give a satisfactory one. Diphtheria, scarlet fever and measles were given as types of con-

tagious diseases, while typhoid was the great example of an infectious one. The progress made in the handling of this last-named disease is one of the greatest achievements in modern medicine.

Many of those present can recall the cheering and admiration evoked when we stood on the sidewalks in 1898 and saw our four companies march off to the war with Spain. Fine, strong manhood they were! Some months later we all stood again ready to give them an enthusiastic welcome home. Did we cheer as that column passed through our lines? It was the most appalling sight I had ever seen in Worcester, and that line of emaciated, worn and unrecognizable men moved along more like a funeral procession, some of them too feeble even to sit up. Contrast that scene with the enthusiasm displayed as the columns of the 26th Division passed in review in Boston upon their return from France. Those men returned, many of them in better physical condition than when they went away, having been protected from the ravages of the disease that formerly carried off more victims than the enemy's bullets. When we consider what modern medical science has done to protect mankind against such diseases as typhoid, malaria, yellow fever and others; when we realize that compulsory vaccination has practically wiped out smallpox in the Philippines, and that it is some years since this country has been obliged to close its ports to travel from the West Indies on account of epidemics of yellow fever, is it not disgusting to receive (as many of us very recently did) postal in the name of the so-called "Medical Protective League," asking us to write our Senator and Representatives immediately, demanding that they vote against the bill to compel vaccination in private schools? We prefer to get our instructions from more reliable sources. While hygiene and sanitation have a great influence on controlling contagious diseases, it is hard to explain why these two should select certain diseases and practically stamp them out and leave others as prevalent as ever.

Antitoxin was just coming into universal use in the treatment of diphtheria, and statistics showed a remarkable drop in the mortality rate. Opposition to the use of antitoxin developed in the profession as well as outside, and one of the arguments against its use was that it increased the number of cases of neuritis following the attack. By saving so many more lives it would naturally seem to produce more complications until such times as the profession was awake to the value of the early use of the remedy. Now we hear no more about an increase in the number of cases of diphtheritic neuritis. Pneumonia, on the other hand, is a disease where no marked effect is seen in the mortality rate because we have no specific for its prevention or its cure.

The x-ray has been developed and its present value as a means of diagnosis has all been

reached in the past twenty-five years. I remember the first x-ray picture that I ever saw. It was that of a hand with some rings on the fingers, and the surgeon who showed it related to us how he had seen a silver coin inside a box by looking through a fluoroscope. Little did we realize how great an advance or help this one means of diagnosis was to become.

So, too, with many other methods, some of which we knew about, but which had not then been applied to a practical or universal use, such as the blood pressure apparatus, the electrocardiograph, photography, blood counting and blood chemistry. Radium had not been discovered.

One other thing I want to mention, because I believe it has come to stay, though our views may admit of considerable modification, and that is the theory that foci of disease hidden or untreated may be the cause, or one of the causes, of the rheumatic pains and arthritic changes so commonly seen and productive of so much deformity. If by attention to these foci and the intelligent treatment of them we can prevent the onset or progress of these joint changes no one thing in medicine will bring more relief to sufferers than this. How far we may go, or just where we may be led, may not wholly be apparent now, and we may decide that a chronic cholecystitis, for instance, is just as much a source of danger as abscesses at the roots of the teeth; still, I believe there is more than a possibility of great benefit coming from this theory. Attention to the upper right quadrant of the abdomen has decidedly increased, and it looks as though some men regarded the gall-bladder as about as useful to us as the appendix, and to be gotten rid of if possible.

Along with the expansion in hospital work, and with the changing views concerning disease and its treatment, other things have happened that have had a good effect. With the broadening of our ideas of disease and with the development of means of treatment other than by the use of drugs, the differences between the two most prominent schools of medicine have faded away and, today, we see our brethren of the homeopathic faith sitting with us with no thought on either side but that of good fellowship.

During the past ten years the College of Surgeons and the Association of American Physicians have been organized, both being in a position to exert great influence in shaping public opinion in the future.

The standardization-of-hospitals movement has brought about a more careful interest in hospital work, and has led up to the follow-up system and in many places to the engaging of a social worker. In this way a beginning has been made toward knowing the results of hospital work which will be of inestimable value in the future.

These changes, this expansion, the broadening

of the field of medicine have brought about a condition that causes us to consider where we are headed. Medicine has reached a stage where not only does the practitioner feel his helplessness in trying to grasp the whole, but even in the two great sub-divisions—medicine and surgery—there have appeared men who are being known as having given special attention to one set of organs, so that now we hear of the stomach specialist, the heart specialist, the specialist on respiratory diseases, etc. In this way, while the whole field of medicine has broadened, the individual's endeavor has narrowed. So far as the public is concerned, this attitude has been accepted as reasonable and no doubt beneficial. I think, so far as the patient is concerned, the sum total has been for his benefit and will be more so in the future. There are, however, some dangers and losses that I shall mention later.

We recognize that the great majority of cases seen in practice are cases which present either no difficulty in diagnosis, or the patient's condition is such that the general practitioner can handle them successfully himself. Then there are other cases where the diagnosis is so clear that the doctor consulted knows where to send them if he himself feels incompetent to care for them. There remain, however, many cases where the diagnosis is doubtful or obscure; where the services of a number of men in special lines are needed to clear up doubts before successful treatment can be instituted. It is to meet the need in these cases that the idea of group practice has sprung up, but not only on this account, but because it is recognized that to send a patient to a number of specialists for a collective opinion would be so expensive that it would be prohibitive to all except the rich. The idea is not to supplant the general practitioner, but to act as a consulting or advisory board for him. But could any group of physicians band themselves together, establish a laboratory and furnish all the other apparatus necessary fully to equip themselves for such work and make it a success in a district such as we live in? I think not, for two reasons: first, because a return from such an investment would not be adequate to give a good living unless the fees charged were so high as to prevent people seeking their advice and, second, because there would not be material enough to give that return. Even if one such group were successful their success would be a stimulus to other men to form another group, and a divided field would not be satisfactory for many reasons. Today there are men who undertake to establish themselves as such consultants and are successful because they act as a sort of directing head, referring the patient to this or that specialist as the case requires. Probably most of these men have access to some established laboratory or have made arrangements with a laboratory to do this work for them. This is very different from the arrangement I have just described,

where a set of men associate themselves together and furnish all the equipment themselves and expect to make it pay. I doubt then that the group idea will be a success, especially outside the large centers, except in the connection with some established hospital where there will be access to an equipment already there. And in this part of the country where there are comparatively few open hospitals, the opportunity for such grouping will be confined to those men who hold staff appointments. There are individual men who have established private hospitals and who have, perhaps, associated with them younger men who carry on investigations, and while I do not know the arrangement of such a group as to salaries, etc., I think the success of such an enterprise depends most frequently on the surgical fee or special fees and not upon the diagnostic work done.

I believe the group idea is a good one and will bring forth much benefit for the patient, but I believe its field will be limited to a comparatively few. Today, when we meet a doubtful or obscure case, we say to the patient, "Why don't you go up to the hospital for a study of your case?" And the patient, feeling that he is to derive much benefit from this very careful study of his case, falls in with the idea. He goes and is examined from top to toe, inside and out, and in instances receives decided benefit thereby. Are we not relying on the established hospitals and their equipment in order that the fees may be within the reach of our patients?

As it is, does not this thorough investigation include x-ray work, laboratory work which furnishes examinations of urine, faeces, blood and blood chemistry, kidney function tests, and perhaps electrocardiograms, as well as the services of a surgeon, a clinician or a neurologist, before the patient is turned over to the proper man for treatment or returned to his family physician? The work done may be paid for, but nowhere near the amount that would pay a decent interest on the investment. A collective opinion has been given, which is just as valuable, but is seldom paid for. If a surgical case, and the patient can afford it, the surgeon may get a fee for his operation. Otherwise, the patient goes to the ward and the operation is often done by the same surgeon for nothing. How many hospitals are there that are so well equipped with all the apparatus needed for this work that they do not have to go outside for opinions or work, that are successful financially unless they are endowed or supported by a municipality? This is as it should be, for medical endeavor has been and always should be towards benefit to humanity and never to the sordid view of a money-making scheme. Too frequently, however, we are imposed upon by the public. The public has been educated up to the paying of large fees for surgical operations, but it has not been educated up to paying for a diagnosis,

which is often just as important and may even be more essential to a successful handling of a case. They should be taught. Some form of group practice I believe will come, but I doubt that it will be carried to an extreme successfully.

Among other developments in the past twenty-five years having a direct effect upon the practice of medicine is the work done by the State or municipality. Great advancement has been made by the State through its Board of Health in the production of sera for the treatment of disease, the manufacture and free dispensing of antitoxin for the treatment of diphtheria, the more careful preparation of vaccine that reduces to a minimum the possibility of contamination with foreign material, the establishment of laboratories for investigation—physiological and pathological—and for experimental research. The State has also been divided into districts with a health officer in each, whose business it is to look after the conditions under which men and women work. Nearly all the larger communities maintain laboratories where sputum, urine, faeces can be examined; where Wassermanns can be tested out, and where cultures can be examined and reported upon. Municipalities, also, under the direction of their Boards of Health, have established school inspection and have carried it so far that now, not only is search made for contagious disease, but the eyes, nose and throat are examined for defects, or any malformation or beginning trouble detected and the attention of the parents called to the condition.

The attitude of the public to all this has been too frequently that of suspicion or of looking upon it as meddling, but when the benefit of it all is seen, both from the pecuniary gain and from the betterment of health, much of this opposition has disappeared.

Large manufacturing establishments, upon investigation of the time lost by their employees through sickness or accident, have established hospitals of their own where first aid can be given or beginning sickness detected, thereby saving many hours of lost labor. The results obtained in these large plants have brought about the law requiring plants that employ 100 or more hands to provide some one trained in first aid to give aid to injured persons.

During this same period the Workman's Compensation Act has come into existence. Under this Act the manufacturer is enabled to throw the burden of the case of his injured on other shoulders and devote the time saved thereby to other matters, and the workman receives great benefit in the assurance that there will be something coming to him if he is injured, and that there is not the necessity of going to a court to get justice with the chance of getting nothing. There are many defects in this law and too often a great chance for unjust claims to get in for consideration, but on the whole I think the law has benefited both parties. What about

the doctor? I think the Act has made no great difference with the amount of work the average physician gets. I recall the preparation I made to meet the great stream of accident cases I expected to get on the first Fourth of July after I started to practice, all of which I did not get, and I learned that the vast majority of accidents go to hospitals anyway, and now I get out of town on that day if I can. Did the average physician, who before this Act was not in the employ of some establishment, see any more of accidents than he does now? If he did, I think the difference was slight. When the Act first came into effect many doctors took advantage of it to run up exorbitant bills against the insurance companies, and the companies retaliated by fixing things so that the work should not be paid for unless taken in charge by men of their own selection. This ruling has been changed so that now the injured man has the right of choice as to who is to take care of him. The insurance company is protected by the ruling of the Commission that it should be charged just what the man would be charged if he were to pay the bill. I believe the average physician is not affected much by this Act. On the other hand, I believe the surgeon connected with hospitals is the one who is unjustly called upon to give of his time and effort in the care of these cases without compensation, except as he may be in the employ of some large plant. Some boards of trustees of hospitals, having recognized this, allow the staffs of their hospitals to charge for their services, but the Industrial Accident Board has ruled against this. I believe this is absolutely wrong and that no insurance company should expect to get any work done for nothing.

In 1915 the Legislature of Massachusetts appointed a recess committee to study into a proposal to create old-age pensions and insurance against sickness. This committee held fourteen meetings in various parts of the State, and in 1917 presented its report to the Legislature. There was a difference of opinion amongst the individual members of the committee with regard to the exact framing of the law, the time when such a law should be enacted, and the manner of assessment to establish a fund to meet the expense, but the majority opinion was in favor of ultimately enacting such a law. Other States, notably, New York, Pennsylvania, Ohio and California, have had committees studying this same proposition, but up to this year, so far as I know, no State has adopted the plan. The difference between this plan and the Workman's Compensation Act is that it is proposed to raise the money to meet the expense by assessment on those entering into the plan or on the whole body politic. As to the cost of actually carrying on this work, it is argued that the burden would not be much greater than the community now has to stand. When we consider the number of organizations and societies now

in existence that are directly or indirectly concerned in the care of sick and unfortunate members of society, and the amount of money that is contributed by individuals or firms for the same purposes, perhaps we shall find that it is not a greater burden for the State to take it over and systematize it, but past experience in State management does not give us such a lot of confidence that this plan will do away with the need of the same societies, or the contributions from private sources. After having given this subject a somewhat superficial study, I am of the opinion that some sort of health insurance is liable to be thrust upon us in the future, but whether or not it will be a bad thing for the profession depends largely on the alertness with which we look after our own interests. My purpose is not to take up the pros and cons of this subject, but to consider it only in its effect on the progress of medicine.

One other matter: In the October number of the *Century* magazine, is an article entitled, "Trailing the Robin Hoods in Medicine." As I understand it, the historic Robin Hood was an outlaw and after reading the article one does not wholly grasp the reason for this title. The writer begins by calling attention to the fact that the trustees of Johns Hopkins Hospital have made a rule that the maximum fee charged for a surgical operation should be \$1000. He goes on to discuss the question whether surgeons are profiteers or not, and concludes they are not, that no class of professional men do their work more considerably or conscientiously. He claims that the important point is not the large fees charged rich people, but the general high cost of medical attention. He then suggests that the question of medical attention be discussed in terms of the nation and not in terms of the individual. He prophesies that some day we will zone the country for medical purposes, as it is now zoned for banking purposes. We will do away with private practice and create a health army of doctors adequately supplying each district with sufficient practitioners and specialists so that every inhabitant in the district can have all the attention needed. This health army will be salaried and therefore not in danger of treating one more carefully than another. He considers that the present system puts a premium on disease rather than health. The number and quality of men who serve, the length of time required for preparation, the physical equipment of laboratories would then be determined by the health needs and not on what an institution needs and can pay for. This system, he contends, would relieve the doctor of depending on sickness as a source of income and allow him to turn his attention to the prevention of disease. This system would result in the family sending for the doctor at the first indications of sickness, and enable him to give early attention and as often as he thought necessary with

out being accused of fee hunting, and would mean a larger average income for the profession with less expense to the community.

In the foregoing pages, I have tried to place before you some of the influences that have appeared in the last twenty-five years that are having a decided effect on the progress of medicine. I do not claim to have touched upon all, but have selected those that illustrate to my way of thinking the most important, and these immediately divide themselves into two distinct factors, i.e., those coming from within the profession and those from without. Taking the latter first, we are again able to make a subdivision into those coming from the State and those from the general public.

So far as the State is concerned I believe that where medical matters have been left to the appointed health boards and their work has been unhampered by political influences, there has been a continued progress. The successful building of the Panama Canal, or its completion without an appalling loss of life, depended on the application of the principle of the way in which malaria, yellow fever and typhoid were transmitted. This same principle has been applied successfully to the stamping out of typhus. Hygiene and sanitation were not enough to render Panama safe for work. It needed the study of the habits and habitat of the mosquito and protection against that insect. Neither were hygiene and sanitation enough to stamp out typhus. It needed sterilization also.

I have already mentioned the work of the State in furnishing sera, toxins and antitoxins as well as in establishing laboratories for physiological experimentation and pathological investigation. All these things are in the line of advancement and of immense value to the general practitioner and of great benefit to the patient.

Perhaps the greatest effort of the State health organization has been towards prevention of disease, and in its various departments this work is well done, but its results are, too often, not seen or understood by the public and criticism or open opposition, malicious or otherwise, frequently results. An illustration of this is the present attempt of the State Board of Health to introduce the Schick Test into the schools. Fear and prejudice towards such a thing is but natural and should be recognized and a wise attempt made to overcome it or it will fall prey to some one who has an axe to grind or one who is looking for cheap publicity.

When we come to consider the influence that the general public is having or will have upon the progress of medicine we look back over the past with no great degree of confidence that our aims and motives will be understood. It is not much over twenty-five years ago that anyone who wanted to practice medicine in Massachusetts could hang out his sign and that was all that was required. When a bill regulating the practice of medicine was presented to the Legis-

lature, one of the most prominent Harvard professors appeared against it on the ground that it was infringing on the personal liberty of the individual's right of choice of his physician. The fight between vaccinationists and anti-vaccinationists has existed for years and still exists; so also, with the anti-vivisectionists. Occasionally a new organization like this Medical Protective League is formed with a definite purpose of fighting some progressive medical idea that has undoubtedly passed the experimental stage. Then there are the "real good" people who see only that a measure seems to benefit mankind without giving a single thought of possible detriment to the very object they are desirous of attaining. But, after all, does not this opposition come from a very small minority of the whole, and does not the vast majority of people still have confidence in the medical profession, and are they not willing to be led and to see the value of a new step as soon as they are shown?

As evidence of this, note the gradual acceptance of the practice of inoculation against typhoid, furunculosis, asthma and other diseases, until, I often think, the public has more faith in some of these inoculation theories than the doctors themselves. Acceptance of our ideas or advice may have come slowly and may have produced active opposition, but as a rule we have not failed to gain the confidence of the public and its co-operation. This attitude should be met, as I believe it is being met, with a straight-forward, honest and entirely without subterfuge attitude on our part. More and more the public has been taken into our confidence and our aims laid squarely before them. So when we are confronted with a proposition like national or State health insurance, where our interests are affected we should look upon it from the broad view of citizens just as much as doctors. There seem to be varying views in England, where it has been tried, as to its effect upon the profession, which is the side of it that I am mainly concerned with now, but if I read correctly there is a strong feeling that the whole body politic is better off with law in effect. What I am concerned in at present is the question whether or not it will be a hindrance to progress in medicine. One thing is certain, that, if the public is satisfied that national health insurance is for their benefit, or even this fantastic scheme of zoning the country and making health officers of us all—I brought this scheme in just to show you that such things were being thought of)—if, I say, the public is satisfied that these schemes are for their benefit, they are not going to stop because we do not like them. It is for us to point out to them that anything that tends to lower the standard of efficiency of the doctor is not for their benefit. That is one side that does not always enter into the view of well-intentioned people.

Are there not many drawbacks to such schemes as these, when we look at them from that angle? Under the present system is there a premium placed on sickness? We all know how, as young physicians, struggling to get a start, we have put our best into the care of our patients, because we knew our success and reputation depended upon doing so. Would this be so under any of these schemes? On the other hand there would not be the same reason for a student to so thoroughly equip himself, if he had to feel that after he began practice he would be limited in his ambitions. Would there not be a temptation, as long as the community or State was paying the bill, to make as many visits as possible and run up as big a bill as possible? The patient, no doubt, would not care, for he would be paying just as much whether sick or not, but would he have the same respect for the physician as a man that he has now? If we were all health officers, would there not be a great chance for graft in accepting from the well-to-do extra fees for extra attention? I am not maligning the profession by pointing out that there might be men in it that would stoop to such practices, but I am trying to point out the temptations that would beset him. If we were salaried health officers and conscientiously felt it our duty to watch a case of pneumonia by making three or four visits a day, would we not be in hot water all the time trying to explain to some neurasthenic why so many visits on her were not necessary?

If there is a premium on sickness under our present system, would there not be a much greater one under any such scheme?

Would there be the same incentive for the individual doctor to keep abreast of the times, to constantly study and keep in touch with the best thought of his profession as there is now when his success depends so much on that one thing? It reminds me of the statement of one of our citizens, who had served as an alderman, in describing how a committee from that body went on an inspection tour of our sewerage system. Some of the committee did not get out of the automobiles until they landed at the State Mutual Building, where they were to have dinner!

Our friend of the "Robin Hood" article says that under the existing system of private practice, we have no assurance that every doctor will spend as much time as he should in preparation for practice and no assurance that he will keep constantly in touch with the latest results of research, etc. He also claims, in speaking of medical schools, that in the present system the number and quality of men who serve on medical faculties, and the physical equipment of laboratories, are to a greater or less extent determined by what the institution can pay for, and not by its needs. Do you think that any institution controlled by the Government, with all the chance there is for political intrigue, would select its teachers with any

greater interest for the institution's welfare than is done now? In what field has governmental control demonstrated that it has produced better conditions than exist under private management? Who is responsible for our present laws governing registration in medicine? Are they what we would make for ourselves if we had the whole say?

No law requiring a doctor to take time to study, to visit hospitals, and to take post-graduate courses, would be half so effective in stimulating him to do so, as for him to realize that it was for his own interest to do it.

In the past, the profession has set a standard for itself. It has never tried to restrict the freedom of choice to the individual in selecting a doctor, but it has insisted that, if a man desired to become a doctor, he should go through a preliminary training and not impose himself upon an unsuspecting public. In so far as this requirement fails to meet our ideal, the fault does not lie so much with the profession as with outside influences. In other words, we set a much higher standard than the public would require of us.

Courses in schools have been extended, a better preliminary education insisted upon, clinical teaching and hospital experience have been developed so that now medical schools outside the large cities, where there is an abundance of clinical material, are hard put to exist at all.

Through the efforts of men in the profession, and later through the influence of the College of Surgeons, there has been set up a standard for hospitals, and hospitals refusing to attain or to approach that standard are liable to be advertised for their true worth before the public.

Would there be any better progress if these things were controlled by regulations or laws? If national health insurance comes, it is up to us to help frame the law so that there will never be a breath of suspicion that we can take advantage of it to milk the public fund for all we can get out of it. Let us not make the mistake of viewing any such legislation as apparently some doctors in the beginning viewed the Workman's Compensation Act.

In the days past, the doctor was an individual set aside for a special duty. He was excused from jury duty, he kept by himself and assumed that it was beyond the understanding of the laity to attempt an explanation of medical matters. Today this is all changed and we must assume more than ever the work of taking the public into our confidence. We must become teachers and leaders and it is my conviction that such a course will result in a better understanding of our ideals, and we will not find it more difficult to influence public opinion than formerly. Any attempt to establish health insurance must be met by us in a broad-minded manner and not from a selfish view.

Lastly: what is the effect upon the individual doctor of all this modern medicine? Will ne

be as self-reliant and versatile as formerly? Is there not danger that he will become too dependent upon the apparatus side of it all, and less upon his own individual effort? I heard Dr. W. J. Mayo say once, in speaking of the modern methods of diagnosis, that after all they were only adjuncts to confirm what we could see, feel or hear. He said that a careful history, plus what we could feel with our hands, was of inestimable value because of its effect in keeping us alert. I believe no truer thing has been said. I heard one of our own number say once that we should always endeavor to diagnose a fracture and use the x-ray only as confirmatory evidence.

As I have said before, the student comes forth much better equipped than he was twenty-five years ago, but he has to acquire judgment and discrimination, and these qualities he will acquire by his own efforts better if he aims to do his work alone, learning to select those cases that require more than the ordinary investigation. He will be better appreciated by his patients, he will have shown a deeper interest in his work, and that quality of sympathy so essential to command the confidence and devotion of his patients will not be lost.

I remember, when a boy of twelve or fourteen, our old family physician died of diphtheria. Owing to the malady a public funeral could not be held. I remember the consternation and gloom that settled over the community when it was realized that the doctor was dead. I remember the service some time later in his memory, when the whole township, regardless of religions creed or station in life, assembled in the largest church in town to honor him. Later the people placed a monument over his grave in commemoration of his long years of devotion to them. Dr. Gage told me that his father regarded Dr. Warner of Leicester as one of the best men in this vicinity.

Not so long ago this same feeling was shown when the late Dr. Charles H. Perry died. We remember how his house would not begin to hold the crowds that wanted to attend his funeral. Neither of these two men would be regarded as particularly scientific, perhaps, but they filled a place where they lived, along with a number of others who have passed away, that would be hard to duplicate today. They were self-reliant and versatile. They strove to get into the lives of their patients in a way that scientific medicine never has or never will teach us to do.

Pardon me for citing a case in my own practice, and please do not think I am trying to build a halo around my head for anything I have done. The excuse for bringing this case in, is that it is no more than occurs in the practice of any one of us. I was called upon last July to attend a young girl. I do not intend to go into her case except to say that for three months it was a hard fight, and when a lung condition appeared on top of an abdominal one

I went home one night feeling like a "licked pup." That thin, pale face haunted me day and night. It used to cut deep into the heart to see the appealing look mingled with fear when I did her dressing because she thought she was to be hurt. During it all she never lost confidence and faith that she would get well, and she did. Today as I contrast that pale, thin, appealing face with the full, rosy-checked, almost mischievous one, and the figure that indicates that health has been restored again, I know that I was stimulated to do my best by the trust placed in me.

If scientific medicine ever brings about a condition where true human sympathy is lost, where the regard of the patient for the doctor gives way, or where the close relationship just as often established through working on a hopeless case as on a successful one is not present, then we as a profession will have lost one of the charms that make our work worth while. If what I have just said is regarded as sentimental, and therefore to be scouted at or disregarded, then I am sorry for the fellow who cannot or will not be sentimental. He is the loser.

You all remember the incident in Jan McLaren's story, "The Doctor," where the country practitioner had called a great London surgeon to save the life of one of his patients. The surgeon was met at the station and taken in the "one-horse shay" to the patient. The route necessitated their crossing a swollen stream that meant danger to them both. The great surgeon hesitated and then refused to cross. Do you recall the contempt shown by the less scientific man for the other, and the personality that compelled the great man to do his duty? After the operation was done the surgeon took off his hat to the other, gave him all the credit for saving the life, and said he was proud to do homage to the man who, in the face of danger, had compelled him to do his duty. The opportunity to make true men of ourselves is there, and we should never lose sight of it.

To recapitulate: We see two forces at work today affecting us, one from within, and one from without. These two can be at variance, but they do not need to be. Much depends on our own attitude.

We as a profession must come forward and assume the position of leaders and teachers. We must develop as a body that same confidence in our motives that the individual doctor now often holds in the hearts of his patients. If scientific medicine ever leads us to a point where the finer instincts of our lives are blunted, if we look upon our patients as machines to be taken to pieces and put together again as we will, if it ever leads us to a point where we are out of touch with the sympathy and devotion to ideals higher than science, then we will be the losers.

Preventive medicine has come to the front, and the old saying that we are a profession that

is constantly trying to put ourselves out of business may seem to be true, but it is not wholly true; for, with new fields of investigation opened up, new opportunities have come, and there is work for all. The field has not narrowed but broadened. Our work has changed and become more collective or interdependent, and much less individual. It is not necessary that this new view, this interdependence, should lower our standards or do away with the best of the traditions of an honorable profession. It is because I feel that there is a danger in it that I have written these pages. We can conduct ourselves as a body so that we shall still maintain that confidence from the public that the old practitioner enjoyed, and if we do this we shall have become better men and better citizens for the effort. In this new interdependence are we not liable to discover each other's mistakes more than ever, and does it not behoove us to be more charitable towards each other than ever, and never stoop to the position of trying to "get something" on somebody?

STATISTICS TAKEN FROM THE REPORTS OF FOUR HOSPITALS: MASSACHUSETTS GENERAL AND BOSTON CITY IN BOSTON, MEMORIAL AND WORCESTER CITY IN WORCESTER.

Note that where there has been a discovery of the mode of transmission, or a successful method of inoculation, there has been a marked decrease in the number of cases, with no great decrease in the death rate.

	1895.		
	Cases	Deaths	
Typhoid	461	68	15%
Malaria	105	1	
	1920		
	Cases	Deaths	
Typhoid	105	10	10%
Malaria	15	0	

In diphtheria, on the other hand, where there is no specific for prevention, the number of cases has not diminished, but the death rate has been greatly reduced, because we have an antitoxin for treatment.

	1895.		
	Cases in Worcester	736	Death rate 27.5%
	1920.		
	Cases in Worcester	908	Death rate 6.25%

In pneumonia, where we have no specific for prevention or cure, there has been no decrease in either the number of cases or in the death rate of any account.

	1895.		
	Cases	Deaths	
	459	162	35%
	1920.		
	Cases	Deaths	
	705	250	28%

In appendicitis the treatment has become entirely surgical, and the practice of early operation has resulted in a marked drop in the death rate.

	1895.	
Cases	Deaths	
414	30	8%
	1920	
Cases	Deaths	
1586	33	2%

These statistics have been collected rather hurriedly, and may not be correct, but they illustrate the facts presented.

BACKACHE.

BY WILLIAM DAMESHEK, BOSTON.

DR. OLIVER WENDELL HOLMES defined woman as "a constipated biped with a pain in the back." He must have been exaggerating, but the definition serves to bring to mind a symptom which, with constipation, easily holds first rank both in incidence and troublesomeness with the other ills of mankind.

Thanks mainly to the valuable educational articles written by the manufacturers of Doan's Kidney Pills ("Every Picture Tells A Story"), and by other equally public-spirited manufacturers, the laity has come to believe that pain in the back means "kidney trouble." This is by no means a laughable conclusion when one considers the names that the erudite and scientific medical profession has foisted on this symptom-group: neurasthenie, hysterical, irritable, railway spine; chronic lumbago, uterine backache, static backache; relaxation, subluxation of the sacro-iliac joint; sacro-iliac strain; rheumatism, arthritis of the spine; chronic back-strain, etc., *ad infinitum*.¹

All of this means that pain in the back may be due to anything from psychoneurosis to spinal caries. Every patient with an infectious disease, every case of childbirth, every tired medical student, weary from hours of sitting in hard lecture-room chairs and nights of study, has pain in the back. These are the most common causes of backache, but there are also the *kidney* group of cases; and the *pressure* group, referring to diseases which involve a progressive compression of the lumbar cord or its nerves; aneurysm, neoplasm, tuberculous spine; not to mention the pain referred from various other abdominal organs, and from the organs of the chest. In a differential diagnosis, to be complete, one would start with the skin (herpes zoster) and successively take up muscles, joints, bones, and organs.

The above causes are relatively easy of detection, and are brought out by a carefully taken history and physical examination, com-

bined with laboratory findings. There is a great group of cases, however, which has thus far not been mentioned—namely, the undiagnosed chronic backaches which pass from clinic to clinic labelled in various fashions, treated in various other fashions, and cordially hated by students, internes, and visiting physicians because there are other and greater things to be done.

SYMPTOMS.

The general symptoms of this group can be brought out no better than by a typical or composite case, such as the following:

Case.—A Jewish housewife of 43 years, married, comes to the O. D. D. of the Peter Bent Brigham Hospital, complaining of backache, duration 8 years.

F. H. Negative.

M. H. Husband living and well, 9 pregnancies, 2 miscarriages; 7 children, all living and well.

P. H. Essentially negative.

P. I. For eight years, patient has been troubled with weakness, "nervousness," and general pains and aches, especially severe in the back.

Cardio-respiratory. Dyspnea on exertion, palpitation, no cough, no oedema of the ankles.

Gastro-intestinal. Appetite poor, tongue coated, bowels regular but must use pills daily to make them move. No nausea, vomiting, or distress.

Genito-Urinary. Urinates D 5-6/N O-1. No dysuria or other urinary abnormalities.

Catamenia. Onset 13 years; regular; lasts 3 days; patient must stay in bed for two days with headache and malaise. No menstrual abnormalities noticed. Last period one week ago.

Neuro-muscular. Headache, frontal or occipital, associated with much work and worry. Worries a great deal, especially in regard to her husband, who is very nervous, who always grumbles, and who is never satisfied. Her husband is very passionate, but she tries to avoid his advances because she is so "weak."

Locally. She has had for eight years a dull, dragging pain in the small of her back, worse on standing or walking; occasionally the pain is sharp; there is no relief by any measures the patient may take.

P. E. Negative, except: Abdomen—greatly relaxed and pendulous; Pelvic—lacerated cervix; 2nd degree retroversion; somewhat relaxed pelvic floor. Local—slight limitation of forward and side bending, associated with some pain. There is tenderness on pressure over the lower lumbar region.

On analysis of this case, it will be seen that it has many aspects. Not only is there an *orthopedic* element,—the back symptoms,—but there is a *gynecological* element—the lacerated cervix, etc.; a *medical* element—the constipation; and a *psychiatric* element—the headaches, worries, etc. Were this patient to fall into the hands of a gynecologist, he would repair her

pelvic floor; an orthopedist would give her a corset; a medical man would tell her not to worry and treat her constipation; while a psychiatrist would treat her complexes and laugh at corsets. There is no use in dividing these cases arbitrarily into those due to pelvic manifestations, etc., since in most cases most of the elements will be found mixed.

THEORIES.

Merely for convenience, however, especially in picking out the various theories that have been advanced as explaining indefinite chronic backaches, we may divide them into these classes: Backache, due (1) to traumatism; (2) to arthritis of the spine; (3) to disturbances of pelvic organs; (4) to so-called "relaxation" or "subluxation" of the sacro-iliac joints; (5) to so-called "relaxation" or "subluxation" of the sacro-lumbar joints—spondylolisthesis; (6) to static causes; (7) to neurasthenia.

Backache due to traumatism and to arthritis of the spine can be dismissed briefly. These causes are more or less definite, cause chronic backache, and are treated in various well-known fashions. Arthritis is shown by x-ray, is frequent, but the symptom backache is usually out of all proportion to the amount of arthritis.

Few writers, notable among them Dr. R. C. Cabot,² doubt that disturbances of pelvic organs cause, in some way unknown to them, backache. An interesting explanation of the method by which pain is caused in these cases is given by Reynolds and Lovett³ who, in a joint gynecologic and orthopedic paper, conclude that tenderness of intra-abdominal or intrapelvic organs usually induces the patient to assume a stooping or other strained position in order to relieve the tenderness. This causes pain, by the mechanism later to be discussed.

The theory which has aroused most controversy, and which has been most productive of varied efforts, is that of "relaxation" of the joints in the region of the small of the back. Relaxation of the sacro-iliac joints in association with pregnancy has long been discussed and, as early as 1870, was given as the cause of "distressing symptoms" in that period.⁴ This has been called "physiological,"⁵ and has even been stated to be the cause of backache during menstruation, which has been likened to a "miniature pregnancy."⁶ Not until 1905, however, was relaxation or subluxation of joints made to explain backache in general. Goldthwait and Osgood⁷ asserted that subluxation of the bones forming the sacro-iliac joints was the cause of many of the chronic backaches. They give as symptoms—guarded motions due to involuntary spasm; peculiar attitude on standing; limitation of motion, both forward and side; and abnormal mobility of the sacrum. The peculiar attitude of standing in these chronic cases, and the pain caused on motion, they attribute to the

abnormal position of the bones forming the sacro-iliac joints, causing thus an abnormal tilt of the spine on the pelvis, and pressure on the nearby nerves.

A host of writers thereupon took up Goldthwait's theory, which he further elaborated in 1907,⁸ so that the literature during the next decade is flooded with this newer pathology, and "subluxation," "relaxation," "slipping of the bones," have become almost by-words in certain medical circles.

It is noteworthy that none of these authors give x-ray evidence to support the pathology, although it is self-evident, as Lovett says,⁷ that a displacement of the joint severe enough to press on the nerve-trunks must surely be shown by x-ray. Some of the writers are quite frank in saying that the x-ray is negative in these cases although their diagnosis is relaxation.⁸ Furthermore, autopsy and dissecting-room records fail to bring to light such pathology.

Not alone were the sacro-iliac joints implicated, but it remained for Goldthwait in 1911,⁹ and again in 1913,¹⁰ to bring the sacro-lumbar joint into the limelight. Goldthwait stated that, due to relaxation of the lumbosacral ligaments, the fifth lumbar vertebra could easily slide forward upon the sacrum and be dislocated—spondylolisthesis. The dislocation could take place also to one side with the result that the whole spine would be rotated, the articular process of the fifth lumbar would be drawn into the spinal canal, causing irritation of the nerves inside or outside of the canal and producing thus leg pain called sciatica. It became quite the fad in the last decade to diagnose spondylolisthesis for chronic backache, and even now, in rare instances, the diagnosis is possible if x-ray shows the lesion.

My reason for laying so much stress on this subject is that the osteopaths and chiropractors have taken up the theory of subluxation and nerve pressure and have based all their scientific structure on this—to say the least—dubious pathology.

In 1910, Reynolds and Lovett,³ after three and a half years of research, propounded the so-called static theory. They explain backache by saying it is due to a forward displacement of the center of gravity of the body. This results in an undue strain on the posterior muscles and ligaments, causing pain. *A priori*, the attitude or slouch bringing this about would occur in persons of diminished resistance, of peculiar figures—and it does. As an analogue of the process, we have the familiar pain caused by flat-foot. The sacro-iliac joints may also be involved in posterior strain, causing irritation, and thus pain in the sacro-iliac region. This may rightly be called sacro-iliac strain, but, according to Lovett, it is wrong to assume that this is an entity. All the symptoms referable to the sacro-iliac joints are explained by a *general* attitudinal strain.

Lovett's theory explains most cases, but I cannot see how it explains those chronic cases with definitely limited motions, peculiar attitudes of standing, etc. Here Goldthwait's theory would be useful, if it were acceptable. We will grant the fact that there is normally *some* motion—3mm.—at the sacro-iliac joints (Goldthwait). Is it not possible that wrong methods of standing and walking, repeated small injuries to the joint surfaces, produce a chronic synovitis of the sacro-iliac joints with resulting pain and limitation of motion, as in the synovitis of other joints? Is it not further possible that in the process of healing of this chronic synovitis, adhesions between the sacrum and ilia are formed, thus producing severe pain on motion, extreme limitation of motion, with peculiar attitudes of standing, and with no pathology demonstrable by x-ray? And again, is it not possible that the "snap," "crack," "slip," etc.—i.e., the sound which osteopaths produce on manipulation of most of their patients with chronic backache—is it not possible that this is due to breaking of the adhesions, and that the accompanying relief is due to the fact that the adhesions are broken, and normal motion is again possible?

Thus far I have refrained from mentioning, as a cause of backache, psychoneuroses. I believe that psychoneuroses can cause backache, but only in a roundabout fashion. Psychoneurotics usually have flabby minds, leading to flabby muscles and ligaments, to postural defects, and thus to strain and pain. There is probably always an organic cause, and there is probably always real pain; but, as with everything relating to himself, the psychoneurotic magnifies his pains and aches until they are out of all proportion to his pathology.

Finally, we should consider backache in its relation to other indefinite disorders, also difficult, also shunned by most medical men: namely, constipation and visceroptosis *et al.* There is no doubt that these two are sisters in evil with backache and that the one is inseparable from the others. This assumes importance in the treatment of any of the three—that is, measures must be directed at, not only one, but at all the others.

DIAGNOSIS.

The diagnosis of the type of backache I have been discussing is made partly on the history and partly by exclusion. X-rays should be taken in all cases to rule out hypertrophic arthritis. In women, a pelvic examination should always be made, but conclusions from this should not be too hasty. The individual's attitude, both of body and of mind, is a great factor in the consideration.

COMPLICATIONS.

The complications of backache are three: invalidism, osteopathy, and chiropractic. The so-called healing cults have sprung up as the results of the physician's inability to cope with

such a simple symptom, whereas syphilis and tuberculosis afforded much more opportunity of cure. After all, a patient worries about a *symptom* and wants it removed as speedily as possible; therefore, one cannot blame him for seeking the advice of a man who has helped his friends in numerous cases. In a recent article in the JOURNAL,¹¹ Dr. Macatee states that society has in many of its units found the medical profession wanting; the popularity of the cults represents the individual experiments of these units in their search of the good.

TREATMENT.

I suppose I will be accused of treading where even angels fear to tread when I talk of treatment of this difficult condition. However, is it not a possibility that the orthopedist treats his cases by corsets and forgets medical and psychiatric treatment; that the gynecologist puts the uterus back in place and neglects other measures; and that the psychiatrist treats the complexes and would not think of applying a brace for an "hysterical manifestation"?¹² A medical student is supposed to have an extensive knowledge of practically all of medicine—a bird's-eye-view, in fact,—and perhaps this helps him to evaluate certain data, certain modes of treatment.

With these somewhat apologetic remarks, I will proceed to the treatment. First, a few general statements: The treatment must be absolutely detailed; it must, furthermore, be sympathetic—if the physician *knows* he is going to help the patient, half the battle is won.

As general treatment, plenty of fresh air, good food, and measures to correct constipation and visceroptosis should be considered. Constipation can be treated by various well-known methods, while visceroptosis is treated by exercise, proper methods of standing and walking, braces, etc.

If it is felt that there is a psychoneurotic element in the symptoms, the causes of the neurosis should be thoroughly gone into, and the underlying factors pointed out to the patient, with possible remedies. Merely telling a patient not to worry is probably a useless procedure, whereas explaining to an individual *why* he worries is often of help.

I will not enter into the question of when and when not to use gynecologic methods: firstly, because the subject is so unsettled, and secondly because my knowledge is so meagre. I will merely interpolate a warning given by Chalfant at the St. Louis meeting (1922) of the American Medical Association, which is relevant to the subject.¹²

"The idea that a 'displacement of the womb' is an exceedingly serious condition and may cause symptoms of any kind seems to be firmly established in the minds of people at large. Almost any woman who is not in good health from any cause can be persuaded to submit to opera-

tion when such a diagnosis is made. . . . Too often she is not relieved of her backache until she is fitted with proper support for her sacro-iliac joints; or of her headache, until fitted with glasses, or even of her constipation until her diet is corrected. *These things could be done before resorting to operation just as well as after it* [italics mine], and the patient saved the danger, suffering, and expense of a needless laparotomy. It would seem that at times the benefit derived from this operation is largely due to the enforced rest incident thereto."

As for local measures, a belt or brace has long been known to help. Italian laborers instinctively lower their belts to the level of their anterior superior spines to prevent back strain. Except in the very slight cases, however, mere belts or adhesive strapping are probably of no avail, because they must work through so much muscle and bone. Lovett⁷ advises a corset which is tightest around the bottom, and which furnishes both abdominal and sacral support. The corset should be straight in front and should support the hollow of the back. In addition to the corset, Lovett advises a course of rest in bed for the first few days, and, after the irritation has quieted down for some time, exercises and massage.

An interesting method of local treatment has recently been brought forward, namely, deep normal saline solution injection intra-muscularly, or sacral epidural injection of the same. A description of the latter procedure is given by Ayer in Cabot's "Case Histories."¹³ This method is so new that at present nothing conclusive can be said about it.

Osteopaths treat their cases differently and presumably with relief to many, according to the report of the Committee to Investigate Medical Cults,¹⁴ although the cause of the relief is not known. If my remarks to the effect of adhesions are true, the only rational treatment, then, for chronic cases, with severe pain and extreme limitation of motion, is *manipulation*, and by osteopathic methods. First, there should be a general loosening up of the muscles by swaying the body from side to side, then a quick thrust to the side, followed by a loud "click" or "snap"—the sound, presumably, of breaking adhesions. There is a knack to this manipulatory treatment which very few medical men possess, and if this is valuable, there is no reason why, in this instance, the medical man should not take a leaf out of the osteopath's notebook and treat accordingly.

It will be seen at once that a method of treatment which considers such matters as diet, underlying complexes, methods of standing and walking, manipulations, etc., is a very unwieldy, if not impossible one to handle in a busy out-patient clinic. If such is the case, is it not the fault of the out-patient clinic that such patients are not treated properly, rather than the fault of the treatment? If there are cardiac classes,

diabetic classes, etc., there could profitably be backache classes, where large groups could be simultaneously instructed in fundamental principles.

SUMMARY AND CONCLUSIONS.

In conclusion, I wish to emphasize several points:

1. Backache is probably the most common symptom presented for diagnosis and treatment.

2. The cause of chronic backache (aside from hypertrophic arthritis) is unknown, although it probably is postural in origin.

3. Subluxation or relaxation of the sacro-iliac joints is an explanation not supported by facts, and is probably of extremely rare occurrence.

4. The cause of chronic backache with limitation of motion, peculiar attitudes of standing, and severe pain may be due to a chronic synovitis with the formation of adhesions between the sacrum and ilia. Rational treatment is, therefore, the breaking of these adhesions.

5. Backache is almost invariably associated with other indefinite disorders, such as constipation, visceroptosis, and neurasthenia, and the treatment should include all of these.

6. Backache is slighted and improperly treated by the great majority of physicians and clinics, resulting (a) In great economic loss to the patient (1) who goes from doctor to doctor, (2) who is prevented from doing efficient work, (3) who may become a chronic invalid; (b) in loss of prestige of the physician; (c) in the popularity of the healing cults.

7. Most cases of chronic backache could be properly treated, with good chance of cure, if enough time and thought were given them.

8. The treatment should be detailed and sympathetic. It is (a) *General*—In which measures against constipation, visceroptosis, underlying complexes, wrong methods of standing or walking, gynecology, are considered; (b) *Local*—(1) For mild cases, a belt or adhesive strapping; (2) for more severe cases, a course of rest, and then a tight corset, as suggested by Dr. Lovett; (3) for severe cases, the breaking of adhesions by manipulation—the osteopathic method.

9. Backache could be advantageously treated in classes at the hospital.

I wish to express my gratitude to my instructors, Drs. Elliott C. Cutler and Hilbert F. Day, for their inspiration and aid.

REPORT OF A CASE OF BILHARZIASIS FROM UNITED STATES MARINE HOSPITAL NO. 2, CHELSEA, MASSACHUSETTS.*

BY WENDILL P. CLARE, M.D., CHELSEA, MASS.

The following report of a case of bilharziasis is submitted with the hope that it may prove of interest to other members of the profession, especially those who come in contact with patients from distant parts of the world.

So few cases of this disease have been reported within the United States, especially cases wherein infection has been caused by the *Schistosoma mansoni*, that it is thought a report of this case may prove of interest.

A.A.G., Summer Street, East Boston, Massachusetts. Born—Alexandria, Egypt. Age 23. **Chief Complaint:** Pain in chest on each side; dizziness, cough. **Family History:** Mother living and well, in Alexandria. Father dead, probably of meningitis. **Occupation:** Has been fireman and oiler on steamships since the age of 15. **Past History:** Born in Alexandria, Egypt, 23 years ago. At eleven years of age he left there and went to India, remaining about six months. From there patient went to London, England, and thence to Cardiff where he fired on a steamer between the latter point and the Mediterranean, during three years, following which he came to New York.

For the sake of brevity, the discussion of subjective symptoms has been condensed as much as is consistent with a proper outline of the case. A history of dizziness, infrequent epistaxis and frequent sore throat is volunteered. The patient has also experienced indefinite pain over the precordium, and dyspnoea for some little time previous to entrance here. A persistent, unproductive cough has been a constant symptom during the last year.

Gastro-intestinal symptoms have been confined to irregular constipation and several passages of blood with the stools, since 1917. Terminal hæmaturia has been noticed occasionally since 1916.

Present Illness: In 1920 patient had diarrhoea for four days, having from 17 to 24 movements daily. Stools were of a blackish color and much blood and mucus were present. In August of this year patient experienced pain in epigastrium, difficulty in breathing, weakness progressing, dizziness and fainting spells. Pain of an indefinite type was felt about the region of the heart. Indefinite pains throughout the lungs. Cough and hot feeling in throat. All above symptoms becoming worse, patient sought treatment at this hospital. On entrance to the hospital the patient's temperature was 98.5, pulse 80, and respiration 22. Patient well developed and fairly well nourished, rational, and able to be about.

In the interest of brevity, only positive findings are recorded in the physical examination following: It was noticed that the supra- and infra-clavicular fossae were very prominent, and that each apex lagged perceptibly upon inspiration. Expiration was slightly prolonged over each apex, and the breath sounds were roughened. The heart sounds were of good quality, but the second sound was markedly accentuated over the tricuspid area. Slight tenderness was elicited by deep palpation over the gall-bladder region and spleen. All reflexes were present and normal.

LABORATORY FINDINGS.

Urine: Light orange, 1026 acid, odor normal. Negative for blood, sugar, albumen and bile. Repeated examinations disclosed no ova.

Sputum: Repeated examinations have been negative for tubercle bacilli or ova.

Blood: Wassermann negative. Red blood corpuscles, 5,640,000; White Blood corpuscles, 7,000; Hemoglobin, 100%. **Differential:** Polymorphonuclear neutrophils, 47%; small mononuclears, 22%; large mononuclears, 13%; transitionals, 2%; eosinophiles, 13%; basophiles, 1%. Stain—Wright's. Cells counted—200.

Examination of Feces: Color, greenish gray; consistence, soft; reaction, alkaline; mucus, considerable; blood, slight. Parasites—ova of *Schistosoma mansoni*.

It is only fair to state that in this case pulmonary tuberculosis was thought of, and not without cause, considering the history and physical findings. Repeated examinations of sputum failed to disclose any tubercle bacilli.

The examination of the blood and the finding of an eosinophilia of 13% was the first clue as to the real nature of the disease.

In talking with the patient it was learned that he was born in Alexandria, Egypt, and up to the age of eleven, had always lived there. Bathing was done in the River Nile, and drinking water procured from the same source. Here, then, we

* Accepted for publication by the Surgeon General.

had the possible source of infection with some parasite, as it is well known the waters of the Nile shelter many diversified types. A stool was procured, the study of which in the laboratory disclosed the presence of the lateral spined eggs of *Schistosoma mansoni*. This gave the diagnosis which is consistent with the history, nationality, subjective and objective symptoms of the patient.

A proctoscopic examination was done and no ulceration nor polypi of the bowel were disclosed by this, and, excepting for slight increased redness just inside the anal margin, the result was negative.

A small amount of feces, of a golden yellow color, admixed with much mucus, was obtained, which, upon microscopic examination, revealed in several instances as many as five ova of the *Schistosoma mansoni* per field. An unsuccessful attempt was made to hatch out some of the ciliated embryos from the eggs in this specimen.

TREATMENT.

It was decided to try emetine hydrochloride in the treatment of this case, as a successful treatment of a similar case with this drug had but recently been reported by Bonnet of Paris. Treatment was instituted on September 20, 1921, with an initial subcutaneous administration of 22 milligrams of the drug in 5 c.c. of sterile distilled water. September 23, 1921, second dose of 33 mgm. was given; September 26, 1921, third dose of 44 mgm. was given; September 28, 1921, fourth dose of 55 mgm. was given.

Owing to the painful swelling caused by these subcutaneous administrations, it was thought best to discontinue this method of employment of the drug. Hence, on September 30, 1921, the fifth dose of 66 mgm. was given intravenously in 10 c.c. of sterile distilled water. Dizziness, coming on almost immediately and lasting about twenty minutes, was the only subjective complaint. Pulse and respiration showed no change.

October 3, 1921, the sixth dose of 77 mgm. in 10 c.c. of sterile distilled water was given intravenously.

October 5, 1921, the seventh dose of 88 mgm. was given as above.

October 6, 1921, the stool was examined, and the ova above mentioned were very numerous and easy to find. The stool was of a slate color, and ordinarily soft consistence.

October 7, 1921, the eighth dose of 100 mgm. in 15 c.c. of sterile distilled water was given. On this date, for the first time, the patient stated that he felt better, and that his appetite was improving.

October 10, 1921, the ninth dose of 100 mgm. in 15 c.c. of sterile distilled water was given.

October 12, 1921, the tenth dose of 100 mgm. as above.

October 13, 1921, the patient developed an irritative, unproductive cough, which was, however, amenable to the ordinary treatment.

October 14, 1921, the eleventh dose of 100 mgm. as above. On this date a stool examined showed the ova more difficult to find, and as many as ten cover slip preparations were examined to find one ovum.

October 18, 1921, the twelfth dose of 100 mgm. as above.

October 20, 1921, the thirteenth dose of 100 mgm. as above.

October 21, 1921, a stool was examined, and no ova found in twenty preparations.

October 22, 1921, the fourteenth dose of 100 mgm. as above. On this date it was decided to stop treatment and study the stools daily for any further appearance of ova.

On October 24, 26, and 27, 1921, stools were examined, after magnesium sulphate had been given, in each of which no ova were found.

On the afternoon of October 27, 1921, the blood picture showed: Red corpuscles, 5,490,000; white corpuscles, 26,400; hemoglobin, 96%; *Differential Count*: Polymorphonuclear neutrophils, 36%; small mononuclear leucocytes, 18%; large mononuclear leucocytes, 2%; transitionals, 3%; eosinophiles, 40%; basophiles, 1%. Number cells counted—300. Stain—Wright's.

Attention is readily called to the marked eosinophilia. The patient exhibited his old-time languidness, and his appetite became capricious. His temperature, which had hitherto been practically normal, rose to 38.2 C. and his pulse to 100. A slight friction rub was discovered in the mid-axillary line about opposite the fifth interspace. The left side of the chest having been immobilized by adhesive strapping, the patient was confined to bed, and the condition cleared up in four days.

Stools on October 28 and 29, 1921, were examined for ova without result, but the blood picture on the 29th proved very interesting: Red corpuscles, 5,510,000; white corpuscles, 27,800. *Differential Count*: Polymorphonuclear neutrophils, 21%; small mononuclear leucocytes, 18%; large mononuclear leucocytes, 0; transitionals, 0; eosinophiles, 61%. Stain—Wright's. Cells counted—300. Hemoglobin—98%.

The red cells were of good color, shape, and size. The urine examination on this date was negative. The blood picture of the 31st was essentially the same. The sputum has been continually examined for tubercle bacilli, fungi, and ova of flukes, with negative results.

October 31, 1921, a roentgenogram of the thorax was taken. The report is as follows: Marked thickening about the hila. No definite pathology of lung fields.

November 1, 1921, a stool examined showed numerous ova again appearing, so the emetine treatment was at once renewed, and November 2, 1921, the fifteenth dose of 100 mgm. in 15 c.c. of sterile distilled water was given.

November 4, 1921, the sixteenth dose of 100 mgm. was given as above. The blood picture

on this date showed a remarkable change from that of October 29, 1921: White corpuscles, 18,800. *Differential Count*: Polymorphonuclear neutrophils, 48%; small mononuclear leucocytes, 20%; large mononuclear leucocytes, 3%; eosinophiles, 29%. Cells counted—300. Stain—Wright's. A great reduction in the percentage of eosinophiles.

November 7, 1921, a stool examined after a purge of magnesium sulphate had been given, showed but one ovum in thirty preparations, and this ovum was misshapen and somewhat broken up.

November 8, 1921, the seventeenth dose of 100 mgm. in 15 c.c. of sterile distilled water was given. A stool examined on this date for ova yielded negative results.

November 9, 1921, another stool was negative for ova.

November 10, 1921, the eighteenth dose of 100 mgm. was given as above.

November 14, 1921, the nineteenth, and November 16, the twentieth dose of 100 mgm. was given.

It will be seen from the foregoing that the patient received during the course of treatment 16.85 g.m. of the drug.

November 25, 1921, the blood picture showed the following: Red corpuscles, 5,320,000; white corpuscles, 9,800; hemoglobin, 89%. *Differential Count*: Polymorphonuclear neutrophils, 50%; small mononuclear leucocytes, 29%; large mononuclear leucocytes, 1%; transitionals, 1%; eosinophiles, 18%; basophiles, 1%. Cells counted—300. Stain—Wright's.

The blood had not yet fully cleared up, but such remarkable changes had taken place in it since October 29 and November 4, 1921, that we were led to believe it would become normal.

From November 8 to November 28, 1921, fourteen stools have been examined for ova. Half of this number were natural movements and half followed magnesium sulphate, as it was hoped that in such manner a more fair and true estimate of the condition could be appreciated. At least twenty preparations were made from different parts of each stool, but in no case were the ova of *Schistosoma mansoni* found.

The patient has steadily gained in weight and appearance. He has lost his languidness and is now wide awake and bright. His appetite has returned. His hoarseness has in a large part disappeared. The pain in the region of the gall-bladder and spleen, previously elicited by deep palpation, is no longer present. The signs noted in the chest during physical examination are no longer found.

During the month of December the patient remained under observation. His stools, sputa and urine were frequently studied, with negative results. The blood picture became normal, and upon January 1, 1922, he was discharged from the hospital feeling well in every way.

RECENT PROGRESS IN PHYSIOLOGY.

BY PERCY G. STILES, BOSTON,

Assistant Professor of Physiology in Harvard University.

THE CHANGE OF EMPHASIS.

DURING the past few years one can note a very distinct change in the subjects and methods of physiological research. The science has become more concerned with interpretation than with description. Fewer investigators are engaged in the study of complex coördinated systems, and more are seeking to discover the factors which affect the reactions of isolated cells or elementary tissues. It is as though we passed from observation of an automobile in working trim to an intensive collection of data regarding metals, oil, and gasoline. The new Physiology is less picturesque and more difficult than the old, but it appears to take us nearer to the fundamental properties of living matter. This shift in interest has made it necessary for those undertaking work in our laboratories to come with an equipment different from that which would formerly have sufficed. Detailed anatomical knowledge is rather less serviceable than it was to the masters of the classic period. General Physics and Chemistry now fail to provide the foundation and require to be supplemented by Physical Chemistry and Theoretical Electricity. Mathematics can no longer be shunned by the candidate. In short, the physiologist of the future will be less the naturalist making direct observations upon animals, and more the exact scientist dealing with tabulations and curves.

One feature of this change has been the obvious increase in the importance of Electro-physiology. Not many years ago this seemed a bizarre specialty remote from practical applications. Now it is seen that it promises to throw light on the most intimate mechanisms of stimulation and response. It must be remembered that changes of electrical potential are the only signs of life certainly to be recognized in nerves when disconnected from other tissues. The study of these rapid fluctuations by the ingenious methods now available is steadily making more clear the community of properties underlying the superficial diversity of cellular activities. It is by such technique that Forbes and Miller¹ have recently shown that ether cuts off the ascending nerve-impulses in the medulla. Crile had questioned the efficacy of ether to interrupt the afferent currents, and the latest contribution to the discussion is of the greatest practical interest.

PHYSIOLOGICAL REVIEWS.

It may not be superfluous to call attention to this new publication. The literature has become so voluminous that concise summaries covering special subjects are a necessity. *Physiological*

Reviews is a quarterly prepared for this purpose under the auspices of the American Physiological Society. It is now in its second year. Each volume is to contain about twenty articles written by men at home in their respective fields. Research workers will profit by the extensive bibliography, while a larger number of readers should be interested by the actual content of the reports.

The purpose of the present article is to indicate a few lines of work in which notable progress is being made. There are certain matters of such evident concern to the medical profession that they are not likely to be overlooked. It will be enough to mention two of these: the multiplied studies of the factors in rickets, and the endeavors of investigators at the University of Toronto to obtain in stable form the internal secretion of the pancreas, which is the regulator of carbohydrate metabolism. In these there is high promise of the therapeutic control of diabetes. Without dwelling upon matters so directly related to practice, we will turn to others less likely to be followed in detail by the busy physician.

"ALL OR NONE."

The "All or None Principle" continues to modify our traditional conceptions. Some ten years ago it won its way into our mode of picturing the contractions of skeletal muscle. We then ceased to think of the muscle-fibre as responding in different degrees to graded stimuli. The evidence marshalled by Lucas of Cambridge, England, compelled us to conceive of a slight muscle contraction as the maximal effort of a minority of the fibres, the majority remaining at rest. A little later Adrian showed that a nerve-impulse has the "All or None" character; it cannot reflect the intensity of the stimulus which gave rise to it.

The adjustment of our ideas to the doctrine of Lucas and Adrian has not been an easy matter, but it is gradually proceeding. Any who care to survey the problem may well read a recent paper by Forbes.² A few of the points made by him may be mentioned. If we accept the view that each muscle-fibre responds to stimulation in an "All or Nothing" fashion, and that the same principle holds for each fibre in a motor nerve, we must next ask how it is with the sensory apparatus. Have afferent fibres properties essentially different from those of efferent fibres? If they have not, what are we to think about the relation between stimulation and response on the sensory side? How shall we account for the seemingly smooth gradation of our sensations, and of measurable reflex actions?

Forbes tells us that the evidence will not permit us to think that sensory and motor fibres differ in any important respect. Assuming them to be much alike, we may still admit the following possibilities as we seek to explain how

increasing stimulation of receptive endings brings about increasing responses. First, stronger stimuli take effect on more numerous nerve-fibres. Second, very strong stimuli, though solitary, are capable of developing repeated nerve-impulses. Third, certain rhythms of stimulation favor the penetration of the gray matter by the resulting series of impulses; other rhythms are definitely unfavorable. It would not be profitable to follow the application of these guiding principles to the intricate mechanisms of the central nervous system. It is certain, however, that they will be employed in future analyses.

HIGH LEVEL NUTRITION.

Attention may be called to a protracted study in human nutrition reported by Gulik.³ It deals with over-feeding, and is thus complementary to previous investigations of the results of under-feeding, such as the elaborate one described in Publication 280 of the Carnegie Institution. Gulik made himself the subject of his experiments. By arbitrarily increasing the quantity of his food (without resorting to any artifices to make it more tempting) he carried his daily intake from about 2700 to about 4100 calories. In the course of many months he increased his weight by 10 kilograms, and attained to an equilibrium upon the new diet. Thus he added something like 50 per cent. to his ration, and operated his body with approximately 20 per cent. increase of mass.

These observations are on the whole consistent with the Carnegie findings. Benedict and his colleagues have shown that a man who sacrifices 12 per cent. of his original body-weight may do without some 40 per cent. of his former supply of calories. That is to say, he may maintain the new equilibrium, and still carry out the chief activities of his former program. Doubtless he conserves his muscular expenditures where he can. Summarizing the two studies, we may state that changes in weight are much smaller than changes in energy supply, whether one expands or contracts an allowance that has been habitual. One divergence between the results should be pointed out. Under-nutrition decisively cuts down the basal metabolism; during Gulik's period of excessive intake, this significant quantity remained practically unchanged.

THE PULMONARY EPITHELIUM.

As a rule, the accumulation of new data must be expected to add to the complexity of our conceptions. But now and then a welcome exception is noted: we find our interpretations simplified. Such an instance may be cited in connection with the physiology of respiration. Ten years ago the belief was strongly maintained by Haldane that the pulmonary epithelium can actively promote the movement of oxygen from the alveolar air to the blood. It was

taught that this secretory power came to be exercised at high altitudes and, in large measure, determined the success of acclimatization. An analogy was found in the well-known ability of the swim-bladder of the fish to secrete oxygen, albeit in an opposite way—from the blood to the lumen of the organ.

It has been difficult to credit the delicate endothelial cells of the lung with such a capacity, and it now appears that we are not obliged to make the assumption. Haldane had claimed that the tension of oxygen in the arterial blood of acclimatized subjects living at high altitudes might distinctly exceed the pressure of oxygen in the alveolar air. Such a state of affairs could hardly be explained without invoking a secretory process—an energetic transfer of oxygen to the blood. Careful experiments made last winter in the Peruvian highlands by British and American physiologists have failed to support the secretion hypothesis. Working at 14,000 feet, and using as subjects not only the members of their own group, but also the permanent residents, they found that the oxygen tension in the arterial blood was invariably below that in the alveolar air. Physical diffusion would therefore account for the passage of the gas into the blood.

If we are not permitted to include secretion of oxygen among the processes by means of which the organism maintains itself at high altitudes, we may still recognize the following factors as contributing to the adaptation. The number of corpuscles and the quantity of haemoglobin for a given volume of blood are both increased. The respiratory centre exhibits a modified activity, and by increasing the ventilation of the lungs, keeps the alveolar oxygen pressure nearer to the atmospheric than is the case at sea-level. Doubtless the vasomotor system gives efficient direction to the circulation. Surface relations between the air and the blood appear to be improved, and the permeability of the epithelium is probably increased.⁴

ALVAREZ ON THE ALIMENTARY CANAL.

An interesting monograph of the past year is the book by Alvarez.⁵ In it we have presented a body of evidence largely from original studies, emphasizing the autonomous capacities of the digestive tract. It is impossible in a brief abstract to do justice to the argument. The fundamental thesis is that the canal is normally characterized by a "metabolic gradient"—that the spontaneous rhythm of the musculature is progressively slowed as the successive segments are passed. In other words, we have here a condition comparable to that which we recognize in the heart. The auricle normally inroads to the ventricle, and acts as "pace-maker." We express this by saying that the auricle has a superior rhythmicity; after it has executed a contraction it recovers, and is ready to repeat more promptly than is the case with the ventricle. In the same terms Alvarez would explain the

polarity of the intestine, and the usual advance of the peristaltic waves in a fixed direction.

He holds that reversal of peristalsis is a much more frequent occurrence than has commonly been assumed. It would be expected to set in if the irritability of any intestinal segment should be so intensified as to exceed that of the region next above. Such a change may conceivably result from inflammation. The contention is supported at length, and seems likely to modify long-accepted views. For several years Alvarez has maintained that the sensory symptoms of intestinal disorders are largely the result of mechanical conditions, and not of toxæmias. At this point he is supported by the recent work of Donaldson and his associates.⁶ These investigators, after personal trials involving no little discomfort, conclude that the ill feeling attending constipation is chiefly due to the mass of material distending the intestine, and to reflex disturbances therefrom, rather than to poisonous decomposition products.

DIFFERENTIATION OF MUSCLE.

One of the most revolutionary doctrines now before us is that which is advocated by Carey.⁷ He advances the opinion that the three contrasted types of contractile tissue found in the mammalian body owe their peculiarities to the use to which they have been subjected, rather than to any original characteristics. This is a dynamic theory of development. It suggests that smooth muscle, if persistently acted upon by a force alternately stretching it, and permitting it to contract, should acquire the nature and appearance of cardiac tissue. To test this possibility, Carey has patiently applied a distending pressure to the bladder of a young dog, injecting an antiseptic solution to fill the cavity of the organ, and then allowing it to empty itself. He reports that after a long course of these exercises the muscle cells from the bladder-wall have the microscopic aspect of cardiac elements. Such a finding, if confirmed, will be of the highest importance. It is certain to be rigorously examined.

TUBERCULOSIS OF ANKLE JOINT AND TARSUS.

BY HENRY J. FITZSIMMONS, M.D., BOSTON.

[From the Orthopedic Clinic of the Children's Hospital, Boston, Mass.]

IN the December 17, 1910, number of the *American Medical Association Journal*, Dr. James Warren Sever published an analytical study of the cases of tuberculosis of the ankle

joint and bones of the foot which were on record at the Boston Children's Hospital from 1868 to 1910. In his conclusions he states: "The expectant or conservative method of treatment is preferable to the operative one. Time is saved and deformity less under the conservative plan than by the operative method. There is also less danger of secondary joint involvement and general tuberculosis by pursuing the non-operative plan." Ten years frequently brings forth many changes in the treatment of any surgical condition. In order to check up the results of the treatment of tuberculous lesions in the ankle joint and tarsus at the Children's Hospital, the records were collected of all such cases for the last ten years. There have been treated at the Hospital during that time:

	Spine.	Hip.	Knee.	Ankle.	Elbow.	Total.
Wards	635	462	114	44	6	
O. P. D.	301	273	92	52	9	
	936	735	206	96	15	1,988

From 1868 to 1910 the clinic treated 7474 cases of bone and joint tuberculosis. Of these 7474 cases 213 were of the ankle joint and bones of the foot. In the last ten years there have been treated 1988 cases of bone tuberculosis; 88 of these being involvement of the ankle joint and bones of the foot. From such comparisons, we have become impressed with the fact that tuberculous lesions in bones and joints are not as frequent as they were ten years ago. For example, there have appeared for treatment 88 cases of tuberculosis of the ankle joint and tarsus as against 213 such cases treated in the previous ten years.

Notwithstanding the evidence submitted by Doctor Sever in favor of the conservative type of treatment, the writer has been surprised at the number of cases operated upon before and following admission to the hospital.

To correlate results from the different types of procedure, we have for the last two years, gradually gathered all the tuberculous ankle joints and tuberculous lesions of the tarsus for the purpose of comparison and study, and grouped them into two large classes. In one class have been placed all cases that have received surgical interference. Operations in this group have included all grades, from the simple so-called medical incisions to excisions of one or more bones. In the second class have been placed all cases that have received no surgical interference; and in this group those cases that had abscess formation with spontaneous rupture of the contents without surgical assistance have been included.

There were examined 88 cases; of which 43 were boys and 45 girls. The traumatic factor in relation to the sex of the patient was found to be of very little value in a child under twelve years of age. Under twelve years of age, the activity of boys and of girls is about the same and the opportunity for trauma is therefore practically the same. In this series, the right ankle was

affected 45 times and the left ankle 43 times. In the histories it was noted that the patients had been exposed to tuberculosis by one or more of the members of the family in only $3\frac{1}{2}$ of the cases. The history of trauma was considered of no value and therefore not included in this report.

Patients sought medical aid usually after a definite lapse of time from their first symptom. The duration of the time from their first symptom before medical aid was sought varied from 3 to 12 months; the average being $7\frac{1}{2}$ months. In this regard it is instructive to note that the older the child, the greater the duration between the first symptom and the request for medical aid. This may be partially explained by the greater ability of the bone to support the structures involved.

The diagnosis of tuberculosis of the ankle joint and tarsus in these cases was based upon the following facts: (a) the presence of bone or joint involvement of a chronic nature without a picture of an acute infectious origin or trauma and persistent protection of the joints involved; (b) x-ray appearances which were early suggestive, but not definitely diagnostic; (c) the presence of a positive Von Pirquet reaction; (d) a frequent negative Wassermann reaction; (e) frequent bacteriological and pathological reports of material removed at the time of operation.

The writer appreciates that the weakness of such a paper as this is that only from the operative cases may we obtain material upon which to make a positively scientific diagnosis. However, one must grant to experience and careful clinical observation the right to make acceptable diagnoses.

The tables show briefly and clearly the end results after an elapse of time of the cases treated by operated interference and those cases treated by non-operative procedure. There were 43 cases treated conservatively by plaster fixation, Thomas ring splint, high sole, and crutches. In this survey there were found 45 cases that had been subjected to some type of operation.

Of the cases treated without operation; 12 did not have sufficient data and 6 were still under treatment so must be excluded from any summary of results.

The remaining cases presented the following results:

There were 10 cases under treatment between 10 and 18 months. In this group 1 case developed tuberculosis of the elbow and one developed tuberculosis of the knee. All presented absence of marked deformity or marked restriction of motion. There were 3 cases under treatment for two years; 1 showed slight deformity, and 2 showed no marked deformity nor restriction of motion.

There were 4 cases under treatment for three years; 1 showed slight deformity and slight restriction of motion; 2 showed no deformity of marked degree, but showed restriction of motion;

spine; 1 case of general tuberculosis; and 1 case of tuberculous meningitis.

From a comparison of this data, we feel that the operative treatment of tuberculosis of the ankle joint and tarsus in children is usually harmful. Time is not saved, deformity is not decreased, and motion is not preserved. When the infection is sharply localized so that a direct surgical procedure be followed, it might be of distinct advantage to resort to careful excision. Unfortunately, at present this is not possible, and, therefore, most surgery is to be avoided. Incision of the soft parts in the direction of the supposedly affected bone or joint has not been of any benefit. The abscess which presents itself and which spontaneously ruptures generally protects the surrounding tissues from invasion and from overwhelming infection. The cases in the operative group that were followed by the quickest healing and usually by the best surgical results were those that had been submitted to small incisions of the fluctuating mass of an abscess about to spontaneously rupture.

We are constantly hearing and frequently not heeding the teaching of the basic principle of the "equation of the foot." This "equation of the foot" in a growing child is constantly changing and is always disturbed in such operations as have been observed in establishing drainage or removing sequestra.

Tuberculosis of the ankle joint and tarsus in children should be treated conservatively. Local rest by fixation, protecting against the strain and mechanical pressures which the individual bones or points are subjected to, should be rigidly enforced.

Heliotherapy definitely aids before as well as in the presence of sinuses. Operative interference should be resorted to only after careful consideration and then the plan of procedure should be definitely understood. There is a greater danger of secondary involvement and general tuberculosis following operations than without. A large proportion of cases of tuberculosis of the ankle joint and tarsus get good functional results with very little deformity, but are more likely to get these results in a shorter time by the non-operative procedure.

ACCOMMODATION TO THE ANOXEMIA OF HIGH ALTITUDES.*

BY ALFRED C. REDFIELD, PH.D., BOSTON.

IN the anoxemia which results from residence in the rarefied air of high altitudes one sees phenomena which accompany cardiac and pulmonary disease, stripped of the complicating features which are due to the primary pathological condition. These phenomena have been the object of study of an expedition led by Mr. Joseph Barcroft of Cambridge University, which

has recently returned from the Andes of Peru. There, eight investigators, of which the author was one, enjoyed rather unusual facilities, having at their disposal a laboratory car on the Central Railroad of Peru. This railway climbs from sea level to an altitude of 15,665 feet in a distance of 171 kilometers, then descends to Oroya at 12,180 feet, to connect with a branch line to Cerro de Pasco, which, at an altitude of 14,200 feet, supports a native population of some ten thousand. As the result of this facility, and the coöperation of the officials of the Cerro de Pasco mines, a series of observations was made upon the physiological changes which accompany the recovery from mountain sickness, such as hitherto have never been obtained.

In the Andes the disability, mountain sickness, which most men suffer on coming into the rarefied air, is termed *soroche*. So definite is its symptomatology, so general is its occurrence in these not unpopulous regions, that it deserves some attention as a clinical entity. Its severity is sufficient to give it, in connection with the mining industry, a certain economic importance. While a few men were met who had never felt it, and many who had suffered but mildly, a very large number are so greatly affected as to be completely incapacitated for several days. In at least one authentic instance the *soroche* of a normal, healthy person has been terminated by death. Each case is an individual story and, up to the present, no one has been able to predict who will and who will not be affected. A description of cases of two degrees of severity will serve to picture the chief features of the disorder.

Making the ascent by train, one lightly touched by *soroche* experiences his first symptoms at an altitude of 10,000 feet or more. Lassitude, headache, usually frontal, and growing in severity, and perhaps nausea are felt. One feels cold, particularly in the extremities; the pulse quickens, respiration becomes deeper and more frequent; the face is pallid, lips and nails are cyanotic. On descending from the summit to Oroya, at 12,000 feet, though a marked improvement is felt, one finds himself reduced to a helpless condition of weakness which renders the least muscular effort irksome and productive of shortness of breath, dizziness, and palpitation. The night's sleep is restless, and on waking one feels much as he does on venturing onto his feet after recovering from an acute infection. In two or three days strength returns, the color improves somewhat and all but the more severe forms of exertion may be undertaken without distress. The majority are less fortunate than this. During the ascent the symptoms are qualitatively the same, but frequently more severe, and nausea gives way to vomiting. The night's sleep fails to bring relief; severe headache, gastrointestinal instability, and weakness continue for several days; the body temperature may be supranormal (102° F. by rectum), and at times one is aware of palpitation. Cyanosis

*Read before the Research Club, Harvard Medical School, March 10, 1922.

is marked. After three or four days in bed, relief comes and in a week normal activity may be resumed, though for many days breathlessness follows any unusual exertion and the cyanosis, though diminished, persists.

It is scarcely to be questioned that insufficient oxygenation of the blood is, primarily, responsible for *scroche*. The physiological basis of the production of its various symptoms raises many interesting questions which cannot be considered here. Rather let us consider how it is that the body compensates for the reduced oxygen tension in the atmosphere so that the visitor, who on arrival is reduced to helpless invalidism, in a few days is able to get about, to carry on physiological experiments all day, or to dance away half the night; so that the seasoned engineer or mechanic can do a full day's work; so that the native miner can carry his load of ore up the steep ladders of the mines.

In recent years it has been maintained that the chief factor in this compensation consisted in the development by the pulmonary epithelium of a latent function, the power of secreting oxygen into the blood.¹ As a result it has been claimed that the tension of oxygen in the arterial blood may be kept up, even at an altitude of 14,000 feet, to 90 or 120 mm., that is, to tensions equal to those existing at sea level and nearly twice as great as that of the oxygen which is in the alveolar air at the time. The development of recent methods made it possible to reexamine this question in Peru. There it was found that in no case did the tension of oxygen in the arterial blood exceed its partial pressure in the air of the alveolus, even after three weeks of acclimatization. The arterial blood remained from 81 to 91 per cent. saturated—in contrast to the normal saturation of 95 per cent. which had existed at sea level.

Two other accommodating actions which had previously been described as accompanying life at high altitudes were amply confirmed at Cerro de Pasco.² The first is that the quantity of haemoglobin, or number of red corpuscles, in a unit quantity of blood is increased 20 or 30 per cent. The second is that as a result of an alteration in the activity of the respiratory center, the ventilation of the lungs is sufficient to raise the tension of oxygen in the alveolar air some 15 to 20 millimeters higher than it would have been had the ventilation of the lungs continued as at sea level to maintain the carbon dioxide tension of the arterial blood at 38 or 40 millimeters. As a result the tension and quantity of oxygen in the arterial blood is increased in measure. A second consequence of the increased ventilation of the lungs is that the tension of carbon dioxide in the alveolar air falls to 23 or 25 millimeters.

This is but part of the story. At Cerro de Pasco it was found that when acclimatization was complete the oxygen combining power of the blood had changed. As a result, under a tension of oxygen such as that existing in the alveolar

air at that altitude it now became more completely saturated than it would have, had the blood remained as at sea level. In this way the degree of saturation may be increased about 5 per cent.

One is at once led to search for other alterations which may be correlated with or used to account for this change in the ability of the blood to combine with oxygen. The reduction in the carbon dioxide tension of the arterial blood and alveolar air, already referred to, is suggestive in this connection, for it is known that alterations in the quantity of carbon dioxide present have a great effect on the equilibrium between oxygen and haemoglobin. In fact, a change in the carbon dioxide tension from 40 to 25 millimeters, such as occurs in the arterial blood on going from sea level to an altitude of 14,000 feet, is sufficient to alter the oxygen combining power of the blood in just about the magnitude which was found to occur at Cerro de Pasco. The situation is not a simple one, however, and at present the conclusion cannot be drawn that the alteration is directly due to the change in carbon dioxide tension. The reason for caution is that in the body an important compensation for the reduced carbon dioxide content occurs. If it did not do so the hydrogen ion concentration of the blood would be considerably decreased, for this property is dependent upon the relative quantities of carbonic acid and bicarbonate which are present. In actuality it is found that the decrease in carbonic acid is nearly balanced by a decrease in the bicarbonate of the blood and consequently the reaction is little if any more alkaline than at sea level. In the experiments which demonstrated that carbon dioxide influences the oxygen combining power of the blood, on the other hand, the quantity of bicarbonate was unchanged and consequently the blood became more alkaline as the carbon dioxide tension was decreased. The cases, consequently, are not strictly comparable and judgment must be withheld until more applicable experiments are performed.

The foregoing describes the conditions found in the members of the expedition after a residence of two or three weeks at a high altitude. How much further would these compensations have been developed had they prolonged their stay into months or years? Examination of the Anglo-Saxon mining men and of the native Cerro de Pascoans gives an answer. The former had been in residence at 12,000 or 14,000 feet, save for brief periods, for two to nine years. Of the latter many had been born and lived for generations in the high altitude.

Of the Anglo-Saxons, none showed a tension of oxygen in the alveolar air and arterial blood which indicated that the respiratory compensation had developed further than in ourselves. Nor did any of them exhibit a higher percentage saturation of the arterial blood than did certain members of the expedition. In accordance with this, practically all, and particularly the more

florid types, appeared distinctly cyanotic. Among this group the red blood cell counts also did not exceed appreciably those attained by us during our short stay. These men were undoubtedly capable of much greater exertion than the most fit of the visiting investigators, but the difference was apparently due to such factors as differentiate the athlete from the sedentary worker at low altitudes, rather than to any measurable change in the blood picture.

Turning to the natives of Cerro de Pasco, it is noteworthy that many, especially those of Spanish extraction, exhibited striking signs of chronic anoxemia. Many were cyanosed to a degree not exhibited by the Anglo-Saxons, while clubbed fingers occurred commonly. In the three cases in which the oxygen saturation of the arterial blood was measured, figures were obtained which compared with those from the members of the expedition in whom compensation was least satisfactory (82-86% saturation). In other directions the native Peruvian has acquired characteristics which differentiated him from the Anglo-Saxon. In many the number of red corpuscles far exceeded that found in the most seasoned mining engineer. But of more interest than this, a mere quantitative difference, is the fact that when compared with the European of like stature the native is found to have a chest of considerably greater volume. Whether this modification has become an hereditary character, or is the result of growing up from childhood in a rarefied atmosphere, is an alluring question.

In this as in previous studies of the anoxemia of high altitudes great attention has been paid to the oxygenation of the blood in the lungs. Because a considerable body of data has accumulated concerning this subject, attention must not be allowed to divert from what is really the cardinal problem, namely, the supply of oxygen to the tissues. It is to this end, if any, that the compensations in the oxygenation of the blood are directed.

The problem which confronts the circulatory and respiratory systems is to supply the tissues with oxygen at an undiminished rate when the body is exposed to an atmosphere in which the pressure of oxygen is subnormal. That this may occur it is necessary (1) that the blood contain enough oxygen to meet the requirements of each tissue through which it is circulating, and (2) that conditions shall be such that this oxygen tends to pass across the capillary walls as rapidly as is needed to keep pace with the oxygen consumption within the tissue.

At first sight it would appear that in the degree of anoxemia with which we are concerned it is not the quantity of oxygen which is deficient. To take a normal case, at sea level, the arterial blood is 95% saturated, the venous blood as it returns to the lung may be 65% saturated, the tissues have removed from it but 30% of its total capacity. At an altitude of 14,000 feet had no compensation occurred the arterial blood might

be but 65% saturated, and if the circulation rate and total metabolism remained unchanged, the venous blood as a whole would be 30% less saturated than this, or 35% saturated. This would seem to be a large margin of safety, but it must be noted that it represents the average condition of the venous blood from all parts of the body. Certain organs, and particularly the heart, must reduce the blood far more than this. Whether the margin would be sufficient for these during rest may be doubted; that it would be inadequate during muscular exercise seems very probable.

The chief condition which determines the rate at which oxygen passes from the capillary into the tissues, unless one assumes some secretory power in the capillary wall, must be the mean difference of pressure between the oxygen in the blood and in the cells in question. Unfortunately, this difference in pressure cannot be estimated without a knowledge of the pressure of oxygen within the tissues. We may, however, gain a rough idea of the magnitude of the pressure head of oxygen within the systemic capillaries from a consideration of the oxygen tension in arterial and venous blood. In comparing the conditions observed at 14,000 feet with those obtaining at sea level it was found that the arterial oxygen pressure had fallen from 100 to 55 mm.; the venous oxygen pressure from 35 to 28 mm. Clearly the pressure head of oxygen in the capillaries is reduced, even with the subject at rest and after all measurable accommodations were completed.

How may the various compensatory changes which occur in the blood at high altitudes be evaluated in their effect on the quantity of oxygen available for the tissues and the pressure at which and by which it is made available? The rise in the oxygen pressure of the alveolar air which results from increased ventilation is of obvious advantage, for it will increase commensurately the tension of oxygen in the arterial blood entering the systemic capillaries. And since this increased arterial tension will be accompanied by an increased oxygen content, the removal of a definite quantity of oxygen from the blood in its passage through the capillaries will leave it as venous blood with a correspondingly increased oxygen content and pressure. Because of the peculiar shape of the dissociation curve, the removal of a given quantity of oxygen from the blood will cause a greater drop in the oxygen pressure if the arterial oxygen pressure is high than if it is less so; but even taking this fact into consideration, it may be concluded that a rise in the alveolar oxygen tension will have a considerable effect on the mean tension of this gas in the systemic capillaries.

The change in the oxygen combining power of the blood, which at first sight appears to be such a striking adaptation, is in reality of very little advantage in oxygenating the tissues, aside from the fact that it makes about 5% more oxygen available. The increased oxygen content is held in the blood at no increased pressure, conse-

quently there is no greater tendency for oxygen to pass from the blood to the respiring cells of the body. Similar considerations apply to the augmented oxygen capacity of the blood which results from the increase in the number of red blood corpuscles. There is 20 or 30% more oxygen present in the capillary circulation which is undoubtedly an advantage during exercise, but the pressure which is driving it into the tissues is not directly magnified. In one respect, however, the pressure head is augmented by this phenomenon. Because of the increased capacity of the blood, the removal of a given quantity of oxygen by the tissues will result in a smaller fall in the percentage, to which the venous blood is saturated and consequently to a smaller change in the venous oxygen pressure. One may estimate that an average increase in the oxygen capacity of 20% will serve to raise the venous oxygen pressure three or four millimeters in this way. The polycythemia consequently will have some but not much effect upon the rate at which oxygen is supplied to the tissues.

In the foregoing discussion it has been assumed that the output of the heart and the rate of circulation remained unchanged. If the blood were circulated at a greater rate through the capillary system, this bringing to the tissues a greater quantity of oxygen in a given time, in some measure a deficiency in its oxygen content might be overcome. Moreover, the more rapid the circulation the less oxygen would each increment of blood give up in its passage along the capillary and the less would be the reduction of oxygen pressure in the venous blood. When it is considered that at sea level the blood enters the capillaries with an oxygen tension of about 100 mm., and leaves as venous blood with tension reduced to 35 mm., having given up 25% of its full oxygen capacity, whereas at Cerro de Pasco the arterial oxygen tension may be but 55 mm., and with an equal oxygen consumption the venous tension would fall to 28 mm., it does not seem extravagant to assume that an increase in the circulation rate of one or two hundred per cent. would be required to bring the mean oxygen pressure up to its sea level value. The method which was available at Cerro de Pasco for measuring the output of the heart is liable to errors as large as 20%, but it would serve to demonstrate any change in the circulation rate as great as this. In fact, it showed that the circulation rate does not differ in one direction or the other from the normal value at sea level by more than the limit of experimental error.

When all compensations are considered two facts remain, the implications of which challenge the imagination and point the way toward future investigation. The first is that in the only coordinated individual the oxygen tension of the blood 5 or 10 mm. below normal in the arterial blood and 5 or 10 mm. below normal in the venous blood. The mean pressure head of oxygen in the blood of the systemic capillaries must consequently be less than at sea level. The second

is that the total oxygen consumption of the body at rest is unchanged. How is it that the tissues take from the blood and consume an undiminished quantity of oxygen when it is delivered to them at a reduced pressure? Is there at sea level an unnecessary excess of oxygen pressure in the blood? Or has some unknown compensation taken place in the tissues so that the velocity of oxidation within them is unchanged by the diminished pressure? Has the protoplasm, like the hemoglobin, altered in its affinity for oxygen? These are the problems which future high altitude investigations must attack.

THE CLINICAL SIGNIFICANCE OF SUDDEN ABDOMINAL PAIN.*

BY ALFRED M. ROWLEY, M.D., HARTFORD, CONN.

THE theme of this paper is: Sudden, severe abdominal pain accompanied with shock and followed by muscular rigidity is indicative of a perforative lesion and calls for immediate surgical interference.

The reason I have chosen this subject is because within the last year I have seen several cases presenting the above symptoms in which the surgical treatment was delayed, to the detriment and hazard of the patient, and I am convinced that the operative diagnosis was postponed for too long a time, waiting for the later corroborative signs.

Pain is a relative word used to denote any suffering from discomfort to agony. As here employed, it expresses a sudden, sharp, severe and acute distress, which is generally accompanied with a cry. The cause of the pain is the shock experienced when a foreign substance, the content of one of the hollow viscera, is thrown out into the general peritoneal cavity. The immediate pain is due to the over-distention of the viscera, causing a mesenteric pull, and to the trauma and chemical irritation of the peritoneum, and, I believe, not to the rupture of the viscera, *per se*. For it is well known that the peritoneal covering of the intestine and stomach is not sensitive to trauma, as the bowel may be handled or incised without producing pain, providing there is no tug upon the mesentery, nor irritation to the parietal peritoneum.

The sensory nerve supply of the parietal peritoneum is intimately connected with that supplying the muscle wall, and a tetanic contraction immediately occurs when there has been a peritoneal injury. This persists in a majority of cases, but a subsequent relaxation may occur if the trauma is slight, as that experienced in the out-pouring of gas with but little fluid from a

*Read before the Hartford County Medical Association.

small intestinal perforation; the spasm, however, again reappears if septic peritonitis develops. In this connection it is to be noted that in the artificially produced pneumoperitoneum the patient experiences but the slightest discomfort.

These three symptoms—sudden pain, shock and muscular rigidity—are the cardinal signs of the surgical abdomen. They are, generally, accompanied with other phenomena, depending upon the location and character of the lesion: such as nausea and vomiting and those referable to shock—as cold, sweating skin, pulse of lowered pressure; and rapid, short, catchy respirations, thoracic in character, due to the lack of abdominal mobility, and cyanosis with the expression of the face indicating anxiety and pain.

Later these symptoms may be augmented with others such as obliteration of the liver dullness, rise in temperature and pulse rate, and as the septic peritonitis develops, by a hyper-leucocytosis and increased percentage of polymorphonuclears, their increase generally preceding the total by an hour or two. All these corroborative signs make for a positive diagnosis, but they may not appear for six to eight hours, by which time the operation should have been performed.

I do not wish to minimize the value of the history of the patient, previous to his experiencing pain. This may point to trauma or history of pre-meal distress and often gives a clue to the location of the perforation.

Here, I wish to make myself clear and to differentiate, if possible, between the distress occasioned by a perforation and that experienced in colic, as appendiceal, biliary, ureteral, etc.

The chief characteristic of a rupture or perforation of a viscus is the suddenness of the attack, as a rule, with little, if any, prodromal distress. In a duodenal or stomach perforation there may, or may not be, a history of prolonged indigestion, but the pain experienced following the perforation is entirely different in character from the previous indigestion distress; whereas in the various colics, there are generally anticipatory symptoms. Preceding gall-bladder colic there is generally a heavy, dull pressure and distress in the epigastrium, then the pain of the colic follows, intermittent and increasing in severity with a subsequent lessening in intensity. In appendiceal colic, the first symptom may be epigastric distress, often quite severe in nature and attended with nausea, but the pain is not of the sudden character of perforation and is prolonged, easing on the appendix emptying itself or upon the muscular death of the organ. Even in the very acute fulminating forms of appendicitis, the location of the early tenderness and rigidity, before general peritonitis has developed, will differentiate it from the ulcerative perforations of a viscus into one of the serous cavities. In both of these conditions surgery is imperative.

In the child, the condition of intussusception is attended with sudden pain, shock and some rigidity of the abdomen. This may closely simulate a perforation and may be very difficult to differentiate. In early cases a tumor of the right abdomen can generally be felt. This again is purely a surgical condition.

In adults diaphragmatic pleurisy, hernia, angina pectoris, or the girdling pains from cord lesions may, in exceptional cases, simulate perforative abdominal lesions, but a careful examination and history should clear up the diagnosis.

In the lower abdomen the symptoms experienced by the twisting of the pedicle of a cyst or a pedunculated fibroid, may resemble a low abdominal rupture. In fact, I operated in the New Britain Hospital a few years ago such a case, presenting a low-grade peritonitis with muscular rigidity and found a small fibroid with a twisted pedicle arising from the fundus of the uterus. This patient was seen late and the pre-operative diagnosis was a perforative lesion.

Nothing as yet has been said about the so-called "slow leak" that may occur in the chronic form of perforation—such as in penetrating ulcers of the duodenum. These ulcerations are generally walled off by fat, exudate, omentum or bowel. They are associated with quite severe, sudden pain with little or no shock and the rigidity following is more or less localized. In fact, these symptoms are very typical of other conditions and more nearly resemble the out-pouring of fluid into the lesser abdominal cavity from a necrotic pancreas.

The common causes of perforation of the hollow viscera are—first: penetration by foreign bodies; second: trauma of the abdominal wall, such as occasioned by a blow, sufficient in its force to cause, when transmitted to the viscus, sudden rupture; third: perforation, the result of necrosis, secondary to thrombosis, either pathological or traumatic; fourth: traumatic rupture from over-distention of a viscus from within; fifth: and the most common, the perforation of ulceration due to infection.

Here, I briefly report a few cases seen in the last year to illustrate several of the various causes.

CASE 1.—A. D., male, of South Manchester, Conn.

Seen May 20th, 1921—Physician, Dr. Burr.

Age 44. Occupation: painter. Weight: 160.

Previous History of pre-meal distress and post-meal indigestion.

Present History.—At 11 A. M., while at work, he was taken ill with a sudden, severe epigastric pain, accompanied with nausea, vomiting and shock, with abdominal rigidity. He was given morphine and sent to the Manchester Memorial Hospital. Dr. Burr reported the case to me in the early afternoon and we operated him that

evening, at which time he had intense tetanic spasm of the abdominal wall. The pre-operative diagnosis was a perforative lesion of the stomach or duodenum. At operation a perforation of the duodenum was found and sutured. The abdomen was quite full of flocculent fluid. The opening was purse-stringed and then fortified by omentum. No gastroenterostomy was done as the condition of the patient would not warrant it. He made apparently a perfect recovery. The elapsed time in this case was approximately twelve hours from the time of the perforation to the operation—too long, I believe, but he was strong and well nourished and the fluid escaped was not too infectious.

CASE 2.—I. T., male, age 65.

Entered Hartford Hospital, May 6, 1921.

Previous history of constipation.

Present History—On the evening of May 5th he took an enema—his daughter thought he used a garden hose. Following this he had severe pain in the abdomen and was admitted to the hospital at 7.15 A. M., at which time his abdomen was generally rigid and he was suffering intensely. Temperature was 101.8, pulse 100, leucocyte count 4,800, differential 63 and 37. Pre-operative diagnosis was made of a perforative lesion of the colon. At operation a small perforation of the descending colon was found. The opening was not at the base of an epiploica, nor was there any gross pathology of the colon. The peritoneal cavity was badly soiled by the escape of fluid. The perforation was closed at operation and the abdominal cavity was drained. Death resulted the following day. The length of time elapsed between perforation and operation was approximately eleven hours, altogether too long a time, and yet he probably had a lethal condition, from the general flushing of the cavity by an enema through the perforation of an organ containing the most infectious bacterial flora.

CASE 3.—J. W., male, age 28. Occupation: fruit salesman.

Entered Hartford Hospital, March 2nd, 1921.

Present History—Yesterday while at work, patient was carrying a box in his arms. He fell and landed with considerable force against the box, injuring his abdomen. He suffered intense pain. He went to his home and his physician, Dr. Conch, sent him to the hospital, at which time his abdomen was generally rigid. His temperature and pulse on admission were normal. The pre-operative diagnosis was a traumatic, perforative lesion of the bowel. At operation a rent was found in the terminal portion of the ileum. This was closed. The general abdominal cavity was drained. The patient made an uneventful recovery. There was considerable elapsing of time in operating this case because of the patient not realizing that he was dangerously hurt and he delayed calling his physician.

CASE 4.—J. R., male, age 55. Occupation: farmer.

Entered Hartford Hospital, June 26th, 1921.

Present History—The day before, about 4.30 P. M., the patient was struck in the abdomen by a wagon pole, at which time he experienced severe pain, followed by intense distress. Immediately after the accident the patient vomited. On admission there was generalized spasm, some retraction and tenderness over the whole abdomen, most marked in the right iliac fossa. Leucocyte count 15,800—differential, 88/12.

Pre-operative diagnosis—Traumatic rupture of the bowel.

At operation the peritoneal cavity was found filled with intestinal fluid. In the right abdomen the intestines were adherent with fibrous exudate. A perforation was found near the terminal ileum. The opening in the bowel was closed and the abdomen was drained. Patient was discharged from the hospital August 7th, his wound nearly healed. In September he developed a cough and a tuberculous condition of the chest and he has since died. The elapsed time between the injury and operation in this case was twenty-two hours, and the patient consented to be operated only after great urging by his family physician, Dr. Ebner, and the physicians in attendance at the hospital. The operative recovery was quite remarkable, considering the amount of peritoneal soiling.

CASE 5.—G. R., female, age 31. Physician—Dr. Conch.

Entered Hartford Hospital, August 12th, 1921.

Present History—At 8 P. M. on the evening before admission to the hospital, she was seized with sudden, sharp pain in the lower abdomen. The distress continued. Patient was in a condition of shock. Upon admission she was quite tender in the lower half of the abdomen, with but little muscular spasm. The patient's color was white and she looked nearly exsanguinated. Pre-operative diagnosis of a perforation of a Fallopian tube from tubal gestation was made. Before opening the abdomen she was transfused with 540 c.c. of blood. At operation a rupture was found in the left Fallopian tube near the uterus. Much blood was found in the abdominal cavity. The abdomen was closed without drainage. Patient made a good recovery.

I report this case because it seems to me that such ruptures must be classified under perforative lesions. It belongs to the class of perforations occasioned by the over-distention of a viscus from within. These patients have the symptoms of acute pain and shock, but the muscular rigidity of the abdominal wall is likely to be much less because of the less irritating chemical nature of the fluid evacuated. In these cases, many times, operative interference may be delayed. In this particular patient such

delay was attended by great hazard, as the rupture was near the uterus and she apparently constantly lost blood.

CASE 6.—M. S., female, age 73. Physician—Dr. Bean of Rockville.

Entered the Hartford Hospital on May 23rd, 1921.

Present History.—Three days ago the patient had a sudden, severe upper abdominal pain accompanied by shock and vomiting, since which time she has been in constant distress, presenting a rigid abdomen with obstinate constipation. On entering the hospital the abdomen was found distended and rigid. She had a leucocytosis of 20,000, differential of 86/14, temperature of 103, rectally, and pulse of 80. The pre-operative diagnosis was obscure, because of her age, distention and rigidity of the abdomen, together with the inability to relieve the constipation by enemata. A diagnosis was made of acute obstruction of the bowel from an unknown cause.

At operation a low mid-line incision was made. The peritoneal cavity contained bloody fluid and fat necrosis was present. This incision was closed. An upper right rectus incision was made. The gall-bladder, which contained no stones, was drained. A colostomy was done to relieve the bowel distention. The patient had a long convalescence, and on July 28th under novocain, sutures were taken in the colon to close the colostomy. On August 8th patient was discharged, since which time she has entirely recovered.

I report this case because it represents the rupture of a viscus from necrosis, although not classified as a hollow organ, yet the out-pouring of a large amount of fluid material into the lesser abdominal cavity may present symptoms closely simulating the perforation of a peptic ulcer. The differentiation generally can be drawn, however, and a diagnosis made if these cases are seen early. They are attended with sudden pain, shock and some abdominal rigidity, but the maximum pain is often to the left of the mid-upper abdomen, attended with cyanosis and some respiratory distress, together with pain in the back, particularly on the left side.

CASE 7.—C. C. McE., Jr., male, age 27.

Entered the Hartford Hospital, Sept. 2nd, 1921.

On the service of Dr. E. A. Wells and Dr. J. B. McCook, to whom I am indebted for the privilege of presenting this case.

Present History.—The patient had been in bed at home for two and one-half weeks with a diagnosis of typhoid fever. At 4 A. M. on the day of admission to the hospital he complained of severe, sudden abdominal pain, accompanied with shock, cold and clammy skin and rapid and feeble pulse. He was seen by Dr. McCook, who said that at the time of the first examina-

tion the patient had some abdominal tenderness and some muscular rigidity. He was brought immediately to the Hartford Hospital, and on entering the hospital one hour later, all the abdominal tenderness and muscular rigidity had disappeared. He had a leucocyte count of 3,600 at 7 A. M., differential count of 63/37. At 2 P. M. his leucocyte count was 8,500, differential 85/15. At 7.30 P. M. he had a total count of 7,000, differential 82/18. During the early evening of the day of admission the abdomen was becoming rigid and an operation was performed by Dr. E. A. Wells. An ulcerated perforation of the cecum was found. There was a small amount of fluid in the abdomen, the intestines were inflated and the patient's condition was poor. The perforation was closed. After the operation he was transfused with saline solution. Death ensued on the following day.

This case, to my mind, is by far the most interesting that has been reported, as it illustrates the point that a small perforation may be attended with sudden pain, shock and slight muscular rigidity. All of these symptoms may disappear if the chemical irritation has been slight, only to reappear as the peritonitis develops. It also emphasizes the necessity of opening the abdomen when such symptoms have early been seen.

The diagnosis of perforative lesions, superinduced upon such an enteric infection, is most difficult, as this case illustrates, and only the smallest percentage of cases of typhoid perforations can be saved, even if the operation is performed at the earliest moment.

The percentage mortality demonstrated in military and civil surgery shows that if the perforative lesion of a hollow viscus is operated within the first six hours a recovery may be expected. After a longer elapsed time the percentage of recoveries rapidly falls.

In writing this paper I have had one thought in mind,—to emphasize the necessity of not waiting for the corroborative symptoms of hyperleucocytosis, increase in temperature and pulse rate and the obliteration of the liver dulness, but to consider the three important signs of sudden, acute pain, shock and muscular rigidity, and upon these to advise and do an immediate operation.

ERYTHEMA MULTIFORME BULLOSUM CAUSED BY ARSENIC. REPORT OF A CASE.

BY WILLIAM J. MACDONALD, M.D., BOSTON.

Attending Dermatologist to Carney Hospital.

Erythema multiforme is an acute inflammatory disease characterized by a reddish, macular-papular or nodular eruption, which may

rarely become vesicular or bullous. The individual lesions vary in size and shape. The onset is sudden, and it attacks the extremities, as a rule, but may be more or less universal. The eruption is not markedly pruritic, is usually self-limited, and the cause has to be sought for with relentless diligence, for it is oftentimes very baffling. In the dermatological out-patient department at Carney Hospital, the disease crops up occasionally, especially at the present time, when the school children are being vaccinated in thousands. The macular-papular type of the disease is that most usually seen. The bullous type is not common. The following case presents an interesting etiological factor.

REPORT OF CASE.

M. R., female, aged 40 years, was admitted to Carney Hospital on June 7, 1922, in the service of Doctor Edward J. Denning, who referred the case to me. The patient presented an acute bullous eruption of the palmar and dorsal surfaces of the hands and fingers, and the plantar surfaces of the feet. She complained of itching and a feeling of tension and burning, but no pain.

The bullae varied in size from that of a pea to the dimension of a pigeon's egg. They were very tense and, from confluence, some were multi-locular. The skin, raised over the tense bullae, was pale and white. The eruption was confined to the parts mentioned. The contents of the bullae consisted of clear serum.

Nine days previously, on May 30, the patient had consulted a dental surgeon. A carious tooth was treated and an arsenical preparation was inserted in the tooth for the purpose of devitalizing the nerve of supply. Two days later, on June 1, she noticed that her hands and feet were slightly swollen and were itchy. On June 5, she consulted a physician and was given Fowler's solution, four minims thrice daily, after meals. After the fourth dose she fainted, for the first time in her life. On the same day, the bullous eruption suddenly appeared. She was admitted to Carney Hospital on June 7.

A general physical examination revealed a fairly good state of health, and an entire absence of past accidents, injuries, or operative procedures. Temperature on admission was 99.8 F. On June 13, 14, 15, 16, it rose to 101 F., but fell to normal on the latter date and remained normal for the remainder of her stay in hospital.

Pulse rate averaged 90 per minute up to June 16, when it became and remained normal.

Alimentary System: Beyond an injected condition of the gums, oral mucous membranes, fauces, and palate, and a chronic intestinal crisis associated with haemorrhoids, nothing abnormal was discovered.

Cardio-vascular System, normal.

Respiratory System, normal.

Genito-urinary System, normal.

Urine: 1025, acid, trace of albumen, no sugar, bile, blood, or pus. Color was amber. Microscopical examination showed a considerable number of leucocytes and squamous epithelial cells.

Teeth: Pyorrhoea about the lower centrals and laterals. An x-ray picture showed periodontal infection about roots of the upper right bicuspid.

Skin: Patient had a past history of eczema following the use of "Metol" used for photographic purposes.

TREATMENT.

Diet: Liquids, non-protein.

Internal Medication: High rectal enemas twice daily for the first week. Atropine sulphate, gr. 1/120 hypodermically at night. Magnesium sulphate, half an ounce twice daily.

External Treatment: The bullae were opened and the affected parts soaked in hot 1-5000 potassium permanganate for fifteen minutes twice daily, followed by crude coal tar. Crude coal tar, 1 part; zinc oxide, 1 part; cornstarch, 8 parts; petrolatum, 8 parts.

June 9, decided improvement followed the relief of tension consequent on opening the bullae and the local treatment just detailed.

June 14, the eruption had passed into a sub-acute stage associated with a denuded epidermis and a few outlying pea-sized bullae. Carbolic lotion 1-1000 now replaced the tar, the parts being kept moist with the application.

June 21, the eruption having practically disappeared, our purpose was now to get the hands and feet in a suitable state to travel, as the patient was due to sail for France in a few days. This was accomplished by means of alcoholic lotions.

July, recovery; discharged from hospital.

September 2, writing from Paris, the patient reports that she has had no further trouble, and that her hands and feet have completely recovered.

BENJAMIN FRANKLIN AS A MEDICAL CONTRIBUTOR.

It appears, according to the *Journal of the Florida Medical Association*, that in Franklin's day there was little or no medical literature in America; that in 1755 he invented bifocal lenses and a flexible catheter, and contributed to the treatment of nervous diseases by electricity. He wrote on deafness, gout, sleep, lead poisoning, heat in the blood, infection from dead bodies, death rate in infants, and medical education. He wrote a history of the Pennsylvania Hospital, of which he was the principal founder (1751). He also wrote a pamphlet on inoculation in smallpox.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

PNEUMONIA.

THE *Bulletin* of the Chicago School of Sanitary Instruction, issued by the Chicago Department of Health, warns of the imminence of the pneumonia season and announces that the Department Laboratories are prepared to furnish specific antigens for Types I, II, and III, and also a combined antigen for Group IV, to be administered subcutaneously for both prophylaxis and treatment of the disease.

Osler's Captain of the Men of Death has ridden triumphantly among us for many years, his toll of lives scarcely affected by the earnest attempts that have been made to unseat him. Now that the vanguard of his army is sending its scouts through crowded cities and scattered hamlets it may be well to take account of stock and see what are our most effective weapons of defense.

SPECIFIC TREATMENT.

Specific antigens or vaccines have seldom been proven of great value in the active treatment of acute infectious diseases. Pneumococcus vaccines for treatment and prevention have been experimented with largely, and their use often been advised, as is apparently being done this fall in Chicago, but strong proof of their efficacy in their present stage of development is still questionable. It is not our purpose to

discourage attempts in this still fruitful field, but it would be unwise to place too much reliance on an insufficiently tested weapon.

The Rockefeller Type I serum has been extensively used and has apparently met with considerable success in the treatment of favorable cases of this type of lobar pneumonia. Its use, however, even in the specific type, is limited, and some investigators entertain doubt as to its practical value. The secret of its success, where success has been attained, rests in its earliest possible administration, as with antitoxin. After the fourth or fifth day of the disease little benefit may be expected from its use. The case must be typed early, serum injected according to the Rockefeller technique, with due regard to the dangers of a preëxisting protein sensitization, and the dose must be repeated at frequent intervals as long as the temperature stays up, or until at least six doses have been given. As with all our biologic therapy or with our therapy in general, to a greater or less degree, the possibility of failure must be reckoned on.

Potent and effective sera have not yet been developed for Type II and III pneumonias, and Type IV forms a heterogeneous group that does not lend itself to specific antibody formation.

GENERAL TREATMENT.

The general treatment of pneumonia has been one of the duties of the practitioner since the day of Hippocrates, and but little need be said concerning it. Fresh air has been indicated in all respiratory diseases, but we believe that the use of cold fresh air may be abused. Zero temperature may be an ordeal difficult to endure, and we would make a plea for moderation in this respect. Fluid should be forced, nutrition maintained, and distention avoided; further treatment concerns the comfort of the patient, which can often be attained by the use of the head-rest, the chest swathe, and the judicious employment of sedatives and narcotics. Many men still make a routine practice of cardiac stimulation. In extremely dyspnoic cases oxygen, by the Barash method or with the mouth tube, is a factor for comfort and may even turn the tide of life or death. Empyema must always be suspected with a prolonged temperature or increased respiratory embarrassment, but without increased discomfort the use of the needle may be cautiously delayed. Empyema, unless extreme, should not be operated on in the presence of pneumonia. The prognosis of streptococcus empyema is improved by closed drainage, as was strikingly shown in army experience.

PROPHYLAXIS.

Pneumonia is a specific contagious disease and suitable precautions should be observed.

The following reasonable suggestions are published in the *Chicago Bulletin*, previously mentioned:

"1. Be regular in your habits of living as to diet and proper rest.

"2. Avoid undue and prolonged exposure to wet and cold.

"3. Get as much exercise in the open air as you can.

"4. Dress so that you will feel comfortable in the house and equally as comfortable when out of doors in a lower temperature.

"5. Keep your living rooms at a temperature not exceeding 70 degrees. For people in normal health and properly clad, 68 degrees is better.

"6. Keep your feet dry and warm.

"7. Do not cough or sneeze in anyone's face or allow others to cough or sneeze in your immediate presence.

"By observing these suggestions you can greatly lessen your chances of 'catching' pneumonia and be more likely to get through the winter without needing the services of the undertaker."

POOR CALIFORNIA AND FORTUNATE WASHINGTON.

THE *Journal of the American Medical Association* commiserates California because its people "can have their backbones chiropractically analyzed and adjusted and their inflamed appendixes osteopathically rubbed to the point of rupture." The writer should have added that their cancers can be manipulated and stimulated to added activity, that children may die of diphtheria, that typhoid fever, smallpox and other communicable diseases may be spread and a host of other diseases with recognized pathology may progress, while the deluded unbelievers in scientific medicine are under the control of these inadequately educated practitioners. History has demonstrated these assertions.

In contrast, Washington is to be congratulated for the repeal of the law passed in 1921 which exempted school children from physical examination. The *Journal of the American Medical Association* reports that the objectionable statute was said to have been enacted as a result of the work of the Christian Scientists.

All honor to a state in which public sentiment has been developed to that degree of intelligence that makes possible the overthrow of ignorance and prejudice! Christian Science doctors should join forces with the Holy Rollers. They might then succeed in promoting greater sacrifices of human life.

A LAY EDITOR'S VIEW OF THE NOSTRUM EVIL.

Capper's Weekly, a Minnesota paper published by Senator Capper, has been publicly denounced by the Fairmont (Minnesota) *Daily Sentinel* as a paper claiming for its motto "A Champion of Human Welfare," but containing "column after column of the vilest, lowest, basest, most misleading, deceptive, dishonest and debauching advertisements of nostrums and alleged cures of diseases that are contained in any paper in the United States that is permitted to circulate through the mails."

It is encouraging to find lay editors who will come out boldly and say what they think about the type of fraudulent medical advertising that is still printed in so many publications. The American Medical Association is doing its best to protect the country against this sort of deceit. We welcome to the ranks all others who will aid in this much needed housecleaning.

DOCTORS AS SUCKERS.

One of the definitions of the word "sucker" found in Webster's Dictionary is "A person easily duped." Therefore, this opprobrious term may be used in English composition. Whether it may be applied to doctors may be open to debate, but it is a fact that physicians and clergymen are quite generally believed to be easy marks for unscrupulous vendors of stocks and often become the victims of schemers who hold out alluring promises of fabulous returns from alleged investments.

The inspiration for these remarks is found in a circular forwarded by a prominent member of the profession, with the suggestion that a brief discussion of the pitfalls prepared for the unwary may be in order. This circular is printed on good paper and sets forth that the recipient is invited by a board of directors to indicate his interest by signing a card which suggests that "You may favor me with details of this enterprise at your earliest convenience." Among the list of directors may be found the names of men with imposing scientific, business and literary titles and associations.

As usual, the advertised corporation has been formed for the purpose of manufacturing a product according to a process which places it at an advantage over all competitors. The implied suggestion is that investors in the stock will secure enormous profits.

We hope that those physicians with the gambling fever, who have been led to invest, will realize large returns, but we would like to suggest that in the future the rule should be adopted of making a careful analysis of opportunities for investment before parting with hard-earned money and never buy undeveloped prospects.

Too many young physicians put money into unsound enterprises with the hope of large profits. We contend that sick people should always consult expert advisers. In turn, physicians should consult business experts when they have money to invest. The speculators and plungers, as a rule, do not succeed financially. The man who puts his money in savings banks and government bonds will, ninety-nine cases out of a hundred, be better off when he reaches sixty years of age than the man who responds to alluring circulars. If one cares to go beyond absolutely safe investments let him go to a house with an established reputation for prudence and business sagacity. Even then, the man who invests in stocks is very fortunate if he never suffers loss. Finance is an intricate and complicated problem and some of its most brilliant exponents have suffered great reverses.

Our advice to the doctor is to play the financial game safe and spend energy on the practice of medicine, exercise business acumen in collecting accounts and invest only in recognized sound securities. Careful attention to the practice of medicine, coupled with industry, will almost invariably bring larger returns than speculation. Avoid the danger of loss with its attendant distracting anxiety. Do not enter the sucker class.

THE NEW PEDIATRIST.

Dr. L. Emmett Holt, president of the Child Health Organization of America, in addressing the American Child Hygiene Association last October sounds perhaps not a new, but an important note in stressing the need for a new type of pediatricist, one who knows not merely the diagnosis and treatment of the diseases of childhood, but the growth, development, and needs of the normal child, physical, mental, and educational.

Dr. Holt has emphasized the need of all time and happily the trend of the present time. Prevention is more important than treatment, and hygiene than pathology, and only by the understanding of the normal can we understand either. Herein lies the great failure of modern medical training, for the medical school teaches little but disease, and the hospital ministers only to the sick. This need is perhaps most keenly felt in Pediatrics, for Pediatrics should be essentially the prevention of disease and the regulation of normal development.

How much does the interne, freshly graduated from a Pediatrics Hospital service know about the minutiae of normal maternal nursing? The use of protein milk in acute indigestion with diarrhoea he is thoroughly familiar with, as he is with the interpretation of serum protein concentration and the indication for in-

travenous glucose. Should my boy play football? Will rowing injure his heart? Such questions are undoubtedly often asked and presumably always answered, but on what real knowledge of facts are the answers based? These questions may sound trivial, but they serve to exemplify the position in which the embryonic scientific pediatrician will find himself some day.

A BETTER CHANCE FOR THE BABIES

The Metropolitan Life Insurance Company's Statistical Bulletin for October points out that the first month is the most dangerous period of life. It is easier to survive a year at the age of 65 than for an infant to live through its first month. In the United States each year over 105,000 babies die before they are a month old. Infant mortality after the first month has been cut in half by better infant care, but that during the first month has been little affected. That this can be greatly improved has been shown in experimental groups. The obvious methods are better prenatal care, reducing the number of premature and still births, better obstetrics, and better care during the entire puerperium.

CHOLERA IN THE PHILIPPINES.

Epidemic and endemic cholera in the Philippines, according to L. Lopez Rizal, Philippine Health Service, in the Monthly Bulletin of the Philippine Health Service for June, 1922, is due to vibrio carriers. It has been found that the vibrio may persist for years in man, during which period it undergoes changes as to its agglutinability.

The problem of disinfecting carriers has not been solved and is a task to which the Health Service has set itself.

SMALLPOX IN THE PHILIPPINES.

Smallpox has never disappeared from the Philippines, but its incidence has been greatly checked since compulsory vaccination was begun years ago. Its persistence in endemic form and the epidemics of 1918 and 1919 are due to the difficulty, with a small force and an insufficient appropriation, of adequately vaccinating the provincial population, and especially the large mass of shifting population. A more determined effort is now being made to vaccinate the small children, believing that in this way an immune population can eventually be secured.

DR. ARTHUR A. LAWRENCE SUSPECTED OF ILLEGAL PRACTICES.

The *Boston Post* has published an account of the alleged detection of a faro fraud in which it is also alleged that Dr. Arthur A. Lawrence is an accessory in association with James Yearley of Detroit. Some time ago a woman was treated in the Boston City Hospital for conditions following an abortion. This woman stated that the abortion was performed by Dr. Lawrence, but when the case was brought before the Board of Registration in Medicine she declined to identify Dr. Lawrence as the one responsible for her condition. Subsequently a woman investigator testified before the Board that Lawrence had agreed to perform an abortion. This was construed as unprofessional conduct. After many delays secured by attorneys the Board on April 18, 1922, suspended the license of Lawrence for one year.

One attorney for Lawrence developed animosity toward the Board during these proceedings, and attempted to secure legislation designed to inhibit the powers of the Board, but did not secure sufficient support for his recommendations.

If the guilty association of Lawrence with law breakers is demonstrated it will be confirmatory evidence of that quality of mind which leads a man to enter upon a criminal life for the purpose of winning a money stake and will give to that Board evidence which would warrant permanent revocation of his registration as a physician.

The faro game may be more dangerous for a criminal than gambling in connection with maternal and foetal life.

News Notes.

NEW OFFICERS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.—At the last annual meeting the following officers for the year 1922-1923 were elected: President, E. C. Levy of Richmond, Va.; executive secretary, A. W. Hedrich of New York; treasurer, Roger I. Lee of Cambridge, Mass.

SOMETHING BOSTON WILL NEVER HAVE—AN EIGHTEEN-STORY HOSPITAL BUILDING.—On November 5 the corner-stone of the new Beth Israel Hospital, New York City, was laid. This structure is to be the tallest hospital building in the world, with four floors below the street level and fourteen floors above. It will be the last word in hospital design and construction, accommodating easily patients demanding every specialist's care—and all in a ground space of 123 by 181 feet!

DEATH RATE IN BOSTON.—During the week ending November 25, 1922, the number of deaths reported was 226, against 212 last year, with a rate of 15.43. There were 33 deaths under one year of age, against 32 last year. The number of cases of principal reportable diseases were: Diphtheria, 70; Scarlet Fever, 55; Measles, 45; Whooping Cough, 62; Typhoid Fever, 4; Tuberculosis, 39. Included in the above, were the following cases of non-residents: Diphtheria, 8; Scarlet Fever, 10; Typhoid Fever, 2; Tuberculosis, 6. Total deaths from these diseases were: Diphtheria, 4; Scarlet Fever, 1; Whooping Cough, 4; Tuberculosis, 12. Included in the above, were the following cases of non-residents: Scarlet Fever, 1.

PITTSFIELD NEWS.—Dr. B. W. Paddock of Pittsfield is away on his vacation, which he is spending in the New Brunswick woods. He expects to be back at work December 1.

Dr. J. B. Thomas has just resumed practice after a three weeks' vacation in Maine, where he was very successful in hunting.

Dr. J. A. Sullivan of Pittsfield is enjoying a 3 months' tour of Europe.

Dr. W. Carleton Warrick, formerly of Detroit, Michigan, has located in Pittsfield, where he will look after the practice of Dr. F. A. Roberts while the latter is spending his honeymoon on a Caribbean cruise.

A. P. MERRILL.

A WELL-MERITED AWARD.—Dr. W. B. Cannon, Professor of Physiology in the Harvard Medical School, has been awarded a distinguished service medal citation for his work overseas. Dr. Cannon holds a commission of Colonel in the Medical Officers' Reserve Corps. He has been connected with the Harvard Medical School since 1892 and was appointed Higginson Professor of Physiology in 1906. He is a recognized authority in his chosen field. He has written many papers and has given freely of his time in aiding movements inaugurated for the instruction of the public on matters of public health.

His name will always be associated with the introduction of the x-ray method of studying the gastro-intestinal movements, the investigations on adrenal glands, and more recently with the scientific interpretation of the phenomena of shock and its rational treatment. As a teacher of physiology his position is pre-eminent.

TOUR DE LUXE TO A. M. A MEETING. SAN FRANCISCO, 1923.

The Medical Society of the State of New York is busy arranging a tour to the A. M. A. session at San Francisco, June, 1923.

Our President, Arthur W. Booth, M.D., cordially invites all the Delegates and Fellows from the Eastern States who are planning to attend the session, together with their wives, sweethearts, and friends, to join this tour to California and the Canadian Rockies.

Our train de luxe leaves New York Thursday, June 14, 6:00 P.M., arriving in Chicago 3:00 P.M., Friday, where we will enjoy a drive over the Lake Shore and Boulevard System; our train is transferred to the Santa Fe System and we leave at 6:00 P.M.

In Kansas City we have another delightful drive the following morning.

Our next stops are to be Colorado Springs, Albuquerque, Grand Canyon, San Bernardino, with auto drive through Redland, Smiley Heights and Riverside, then to Los Angeles.

Next Santa Barbara, Del Monte, Santa Cruz and the Big Trees, arriving at San Francisco early Monday morning, June 25.

We leave San Francisco, Friday, June 29, 10:00 P.M., stopping at Shasta Springs, Portland, Rainier National Park, Columbia River and Seattle.

We have a day's boat sail up Puget Sound to Victoria and Vancouver, with drive in both cities, after which we take our train and continue through the beautiful Canadian Rockies, stopping at Lake Louise and Banff.

Then on to St. Paul, Chicago and home by the Broadway Limited, arriving in New York, Thursday, July 11, 9:40 A.M.

This tour has everything attended to, and the price will be lower than any individual can obtain.

The luxury and freedom from detail and cares, with the opportunity to make friendships will be appreciated by all.

Our special train will be waiting for us at every stop, autos, baggage transfer and hotels, attended to everywhere except at San Francisco, where the Fellows will probably want to go where their section is located.

To insure accommodations in the best hotels en route we must have one hundred reservations by December 30.

All inquiries are to be sent to Malcolm C. Rose, M.D., Chairman of Committee, 152 West 42nd Street, New York City.

THE COMMUNITY HEALTH ASSOCIATION.

The suggestion has been made that the Instructive District Nursing Association and the Baby Hygiene Association should be combined under the title of the Community Health Association.

This is in the form of a recommendation to the members of the corporations.

Mr. William A. Dupree has been chosen as the head of this association; Mrs. E. A. Codman and Dr. Richard M. Smith as the vice-presidents; Mrs. Morton P. Prince as secretary; and Ingersoll Bowditch and Charles E. Spencer as the treasurers.

The directors are Robert Amory, Miss Mary A. Barr, Miss Esther G. Barrows, Dr. Alice F. Blood, Mrs. J. Gardner Bradley, Mrs. Philip S. Dalton, Miss Emily G. Denny, Mrs. Robert L. DeNormandie, William Ellery, Miss Lina H. Frankenstein, Mrs. L. Cushing Goodhue, Mrs. John L. Grandin, Mrs. N. Penrose Hallowell, Dr. Alice Hamilton, Mrs. John C. Hunt, Mrs. Carl T. Keller, Mrs. James Lawrence, Charles E. Mason, Dr. Francis X. Mahoney, Mrs. Frank H. Monks, Dr. Robert B. Osgood, Mrs. Francis W. Peabody, Miss Gertrude W. Peabody, James J. Phelan, Dr. Stephen Rushmore, Mrs. Richard P. Strong and Felix Vorenberg.

Miss Mary Beard, formerly in charge of the Instructive District Nursing Association, will be the general director. Miss Rand will direct child hygiene and Miss McCann the home visiting department.

HOSPITAL HONORS THIS COUNTRY'S FIRST TRAINED NURSE.

Miss Linda Richards was the guest of honor at the New England Hospital for Women and Children, at Boston, Mass., during the fiftieth anniversary of its training school and the sixtieth anniversary of the founding of the hospital itself. Miss Richards was the first woman to be graduated from this school and at the same time the first trained nurse in the United States.

Miss Richards upon graduation was called to the Bellevue Hospital, N. Y. City, where she became Assistant to Sister Helen, the English nurse who organized it. From there she returned to Boston to organize the training school of the Massachusetts General Hospital, later performing the same service at the Boston City Hospital.

BEQUESTS TO HOSPITALS.

By the death of the widow of Arthur F. Estabrook the provisions of the will of Mr. Estabrook become operative, and the following named institutions, among others, will profit by legacies: To the Massachusetts Homeopathic Hospital, \$100,000; the Children's Hospital, Boston, \$10,000; the Boston Floating Hospital, \$10,000; the Eye and Ear Infirmary, \$10,000; Massachusetts Association for Promoting the Interests of the Adult Blind, \$10,000.

Miscellany.

OPINIONS OF AMERICAN STATESMEN ON EDUCATION.

The good education of youth has been esteemed by wise men in all ages as the surest foundation of the happiness both of private families and of commonwealths.—*Benjamin Franklin.*

Promote, then, as an object of primary importance, institutions for the general diffusion of knowledge. In proportion as the structure of a government gives force to public opinion, it is essential that public opinion should be enlightened.—*George Washington.*

Wide and judicious modes of education, patronized and supported by communities, will draw together the sons of the rich and the poor, among whom it makes no distinction; it will cultivate the natural genius, elevate the soul, excite laudable emulation to excel in knowledge, piety and benevolence; and, finally, it will reward its patrons and benefactors by shedding its benign influence on the public mind.—*John Adams.*

A system of general instruction which shall reach every description of our citizens from the richest to the poorest, as it was the earliest, so will it be the latest of all the public concerns in which I shall permit myself to take an interest.—*Thomas Jefferson.*

DEATH RATES, 1921.

THE Department of Commerce announces that the compilations made by the Bureau of the Census indicate that 1921 was a remarkably healthful year. Record low death rates appear for nearly all areas. The lowest state rate (8.2) is shown for Montana, and the highest (11.2) for Vermont. For cities which at the last census had populations of 100,000 or more, the lowest rate (7.5) is shown for Akron, and the highest (17.1) for Memphis.

SHINGLES AND CHICKEN-POX.

MANY writers have noted an interesting concurrence of herpes zoster and varicella, and have attempted to link the two together as different forms of the same disease, according to C. Eugene Riggs, in *Minnesota Medicine*. According to the theory of some, the organism is the same for both diseases, but blood-borne in the case of varicella, in the spinal fluid in the case of herpes. Instances of chronological relationship between the two are of course not wanting; but is this more than coincidence?

The evidence so far seems insufficient.

NEW AND NON-OFFICIAL REMEDIES.

DURING November the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Non-Official Remedies:

Lederle Antitoxin Laboratories: Mercurialized Serum-Lederle for Intravenous Use.

Charles Leich & Co.: Sulfarsenol.

Mallinckrodt Chemical Works: Barium Sulphate Pure. M. C. W.

H. A. Metz Laboratories: Benzozol.

Parke, Davis & Co.: Silvol.

Arsenobenzol-Dermatological Research Laboratories and Arsphenamine-Dermatological Research Laboratories: These products are now marketed by the Abbott Laboratories as Neorsphenamine-D. R. L. and Arsphenamine-D. R. L. The Council has continued the acceptance for New and Non-Official Remedies under these names.

PUBLIC HEALTH REPORTS (UNITED STATES PUBLIC HEALTH SERVICE) NOVEMBER 3 1922.

VACCINATION OF MONKEYS AGAINST PNEUMOCOCCUS TYPE 1 PNEUMONIA BY MEANS OF INTRATRACHEAL INJECTION OF PNEUMOCOCCUS TYPE 1 VACCINE. (CECIL AND SEFFEN.)

THE intratracheal injection of pneumococcus vaccine affords just as satisfactory an immunity against pneumonia as that induced by subcutaneous or intravenous injections. This method of vaccination with three doses of Type 1 vaccine renders monkeys completely immune against experimental pneumococcus Type 1 pneumonia. The mere spraying of the throat with pneumococcus vaccine will not produce complete immunity against pneumonia in monkeys. The immunity established by intratracheal injection of pneumococcus vaccine is probably cellular in character, since little or no protective substance against pneumococcus can be demonstrated in the serum of monkeys thus vaccinated.

AMERICAN RELIEF ADMINISTRATION.

Moscow.—Flying detachments of Russian physicians to administer salvarsan to sufferers from recurrent typhus, which is increasing with the coming of winter, is the latest emergency disease prevention step taken by the medical department of the American Relief Administration in the district of Rostov-on-Don, according to Dr. Henry W. Beeuwkes, chief of the A. R. A. medical division in Russia.

These "flying detachments" are equipped to administer the salvarsan to fever sufferers in their homes. It has been found that salvarsan is an effective aid in the breaking up of recurrent fever. This disease has increased throughout Russia due to the wet and cold weather.

The A. R. A. medical representative at Rostov reports that sanitary and other health conditions are much improved in Rostov over a year ago.

Information just received at headquarters here from Minsk announces that a surgical hospital at the big refugee camp at Kozreva opened on October 15th.

Asiatic cholera, one of the most fatal of epidemic diseases, has been so successfully combated in Russia by a wholesale inoculation of the population that in the Volga basin and the districts of Orenburg and Ufa, where in 1921 there were 93,784 recorded cases of the disease, this summer saw only 5,386 cases, a decrease of more than 94 per cent. for that area.

It was in this region that the inoculation campaign waged by the American Relief Administration was most intensive. In the Ukraine, where operations started later, and where the inoculations were less frequent, the cholera cases increased, but the falling off in the Volga areas more than offset this increase in the Ukraine and the records show for the summer of 1922 only 67,512 cases of cholera in all Russia (including the Ukraine) as compared with 176,885 cases in the summer of 1921. This is a decrease of more than 61 per cent.

DEPARTMENT OF COMMERCE, WASHINGTON.

MORTALITY FROM CANCER, 1921.

Washington, D. C., November 14, 1922.—The Department of Commerce announces that the returns compiled by the Bureau of the Census show that over seventy-six thousand deaths were due to cancer in the death registration area of the United States in 1921; and assuming that the rest of the United States had as many deaths from this cause in proportion to the population, the total number of deaths from cancer in the entire United States for 1921 was

93,000, while for 1920 the number is estimated as 89,000, or 4,000 less than for 1921.

The trend of the cancer death rate is upward, the rate for 1921 being higher than that for any earlier year in 23 of the 34 states for which rates are shown. The cancer death rate in the registration area in 1921 was 86 per 100,000 population, against 83.4 for 1920. In comparing the death rate from cancer in one state with that in another, the Bureau uses "adjusted" rates in order to make allowance for differences in the age and the sex distribution of the population, because, generally speaking, only persons in middle life and old age have cancer, so that a state with many old persons may be expected to have more deaths from cancer than a state with comparatively few old persons.

The highest "adjusted" cancer rate for 1921 is 99.6 per 100,000 population for the state of Massachusetts, and the lowest is 47.6 for the state of South Carolina.

For a few states adjusted rates have been calculated separately for the white and colored population. In this group of states the highest adjusted cancer rate for the white population is 95.9 per 100,000 population for New York, and the highest rate for the colored population is 90.6, also for New York. The lowest adjusted cancer rate for the white population is 51.5 for Tennessee, and the lowest for the colored population is 36.4 for Florida.

Summarized briefly, the adjusted rates show that the Northern states have comparatively high and the Southern states comparatively low cancer mortality, while there is little difference between the adjusted cancer rates of the white and colored races of the same states. In other words, the white and colored races seem equally susceptible to cancer, but both races seem less susceptible in the South than in the North.

MALNUTRITION AND SCHOOL FEEDING.

Bulletin, 1921, No. 37, of the Bureau of Education of the Department of the Interior, on Malnutrition and School Feeding, shows interestingly and convincingly the need of proper food and nutritional training for school children, and the benefit that is derived from their provision.

Malnutrition has so far been most extensively studied in Great Britain. The grading of nutritional defects has been difficult, but a practical working method, the "Dunfermline Scale," has been devised by Dr. Alister MacKenzie, of Dunfermline, Scotland. According to this scale all children are divided into four groups, as follows:

(1) "Excellent" means the nutrition of a healthy child of good social standing.

(2) Children whose nutrition just falls short of this standard are "good."

(3) Children "requiring supervision" are on the border line of serious impairment.

(4) Children "requiring medical treatment" are those whose nutrition is seriously impaired.

Without a uniform method of diagnosis, however, there is naturally a great disparity in the statistics of malnutrition, estimates of its prevalence running from 1 to 50 per cent. of the school population in communities otherwise similar. The chief causes of malnutrition are given as poverty, ignorance, and disease, malnutrition existing in inverse proportion to the family incomes.

School feeding in France antedated that in England, but it has reached the height of its development in the latter country, the Boer War being largely responsible for bringing the issue to the front. In December, 1906, the education (provision of meals) act was passed by Parliament, the act being predicated on the theory that no child should be deprived of the full value of his education because of lack of food.

Philadelphia is responsible for the inception of the school feeding idea in this country, the first penny lunch having been started in that city in 1898. Since then most of the larger cities have adopted it. Chicago at present has the most intensive school lunch system in America. Boston for years made no provision for lunches in the elementary schools, this task being finally taken on during the war by a voluntary committee as part of the food-conservation work. The high school lunches in this city, however, administered by the Women's Educational and Industrial Union, compare favorably with those of any city in the country.

Dr. William R. P. Emerson, of Boston, contributed the first constructive work in attacking defective nutrition by organizing his nutrition clinics and classes. It is through this work, through instructing children in social hygiene and the values of diets, that the best results will come, and not from the merely temporary provision of such food.

SUBCUTANEOUS ETHER IN PERTUSSIS.

Rocco Mancinelli, in *La Pediatra*, September 1, 1922, p. 801, reports satisfactory results from the subcutaneous injection of ether in whooping cough.

One c.c. was used in the first year of life, 1½ c.c. in the second year, and 3 c.c. in the third year. Injections were given every other day, the number varying from 5 to 10. Marked improvement was found in 38 out of 61 cases.

GROUPING OF MENINGOCOCCUS STRAINS.

The United States Public Health Service is working on the serological grouping of meningococcus strains. As is well known, there are a

larger number of strains of meningococci, differentiated on both their tropin and agglutinin reactions. The problem is to develop a polyvalent serum that will combat the common pathogenic strains, and each year it is necessary to add new strains and eliminate old ones. The organism causing a case of meningococcus meningitis should be cultured and agglutinated with known sera in order that a potent serum may be used for treatment.

Obituary.

JOHN WASHBURN PRATT, M.D.

Dr. John W. Pratt, Resident Physician to the Massachusetts General Hospital from 1886 to 1897, died at his home in Dedham, November 17, 1922, from pneumonia.

He was the son of Dr. Calvin Barton Pratt of Bridgewater, where he was born, February 9, 1854. His brother, Dr. Calvin Pratt, long a practitioner of that town, died there at the age of eighty last June, as noted in the *Journal*. John attended Exeter Academy, spent a year at the Massachusetts Institute of Technology, and took the degree of Ph.G. at the Massachusetts College of Pharmacy in 1877. Entering Harvard Medical School, he served as surgical house officer at the Massachusetts General Hospital during the latter part of his course, and on graduating in 1886 became resident physician. In 1897 he began private practice in Dedham, where he served as Associate Medical Examiner of the first Norfolk District, physician to the Norfolk County Jail and to the Dedham House of Correction. For several years he was secretary of the Dedham Board of Health.

He is survived by his widow, Mrs. Marion E. Pratt, a son and a daughter.

RECENT DEATHS.

DR. JOEL FRANK TRULL, founder of the Trull Hospital of thirty-five beds, in Biddeford, Maine, in 1901, has died in that city, following a stroke of paralysis. The end came on November 22, 1922, when he was fifty-four years old. He was a graduate of Boston University School of Medicine (Homeopathic) in 1894 and had long been a prominent practitioner in Biddeford.

DR. FLAVEL SHURTLEFF THOMAS died in South Hanson, November 26, 1922, at the age of seventy. He was born in that town September 7, 1852, the son of Isaac and Abbie Shurtleff Thomas; attended Hanover Academy and Phillips Andover Academy and Harvard Medical School, where he took an M. D. in 1874. Subsequently he received the degrees of S. B. from Syracuse University (N. Y.) in 1885; S. M. from the same source in 1886, and D. V. S. from McGill in 1890. He joined the Massachusetts Medical Society in 1875 and resigned in 1888. Dr. Thomas married Caroline M. Smith, daughter of Capt. Joseph Smith of Hanson, a veteran of the Civil War, and is survived by her and by a son and daughter. He was

a member of Puritan Lodge, A. F. and A. M., of Whitman; Pilgrim Royal Arch Chapter and Old Colony Commandery, Knights Templar, of Abington; North River Lodge, I. O. O. F., of Hanover, and also a member of the Hatherly Medical Club.

DR. EVERETT THORNTON NEALEY, of Bangor, Maine, died in Grace Hospital in that city, November 26, 1922, of pernicious anemia and nephritis, at the age of sixty-four. He was a graduate of Bowdoin Medical School in 1883, was a member of the Maine Medical Association and the American Medical Association. He had served on the staff of the Eastern Maine General Hospital and was physician to the Bangor and Arrostook Railroad, and for many years county medical examiner. He was one of the first physicians in the city to take up x-ray work. His widow, who was Helen Coombs, and two sons survive him.

DR. CHARLES HERMAN MILLER died at his home in Ashmont, Dorchester, November 23, 1922, at the age of 59. He was a graduate of New York University Medical College in 1891, a member of the American Medical Association and the Massachusetts Medical Society, making a specialty of otology, laryngology and rhinology.

Correspondence.

CANCER WEEK.

(From Our Maine Correspondent.)

Mr. Editor:

The State of Maine during the past two years has instituted and carried on a very active and aggressive campaign for the control of cancer, and it may be of some value for those interested in this subject in other States to know some of the details of Maine's plan of campaign and to learn how practically every adult in a State made up largely of scattered rural communities has had the essential and hopeful facts about cancer placed before him in these two years.

Cancer control work is under the joint supervision of the Maine Medical Association, with a committee of three, and the Maine Public Health Association, with a very much diversified committee of nine; this committee being represented by the secretary of the State Federation of Labor, the State Commissioner of Health, the president of the State Federation of Women's Clubs, the secretary of the Maine Graduate Nurses' Association, the head of the Maine State Grange, and the executive secretary of the Maine Public Health Association, besides the three members of the State Medical Association's committee, the chairmanship of both committees residing in the same man.

In addition to these two very active committees, a county chairman has been appointed in each county of the State to carry on the work with the aid of a sub-committee in each individual county.

Maine is a State of few large cities and, in order to solve the problem of furnishing adequate speakers on this important subject, to avoid the necessity of a few able speakers giving up much time and traveling long distances to cover a wide field, and also in order to provide information which should be uniform in character and voice the consensus of opinion of many authorities on the subject rather than giving the chance for the expression of the more limited opinion of any one man, the committee prepared a carefully worded, non-technical, standard lecture which was sent to every physician in the State together with a letter stating the object of the campaign, the manner in which it was desired to place this lecture before audiences, and asking for co-operation.

The response to this scheme was most gratifying. Many physicians who would hesitate to prepare a talk themselves willingly read the standard lecture many times before numerous audiences, both during the National Cancer Week and throughout the winter. This scheme solved a large problem in this State.

And, further, in order that the physician might be spared the necessity of seeking an audience himself, the heads of the State Federation of Labor, State Grange, State Federation of Women's Clubs, State Nurses' Association, and many other social, church, and fraternal organizations, were asked to notify their various sub-divisions of the nation-wide educational campaign and to request that a special meeting be arranged at which some local physician should be asked to read the standard lecture.

Our committee received immediate and most enthusiastic and efficient response to this appeal, and so thoroughly was this scheme carried out throughout the whole State that we are most gratified to learn that a large percentage of the adult population of the State was reached in this way.

In addition to what the doctors have done themselves, in many sections of the State the doctors' wives, after being properly coached in the matter of answering questions which might arise regarding the lecture matter, have gone before small groups in the churches, normal schools, etc., and read the lecture, thus increasing the number of people reached.

Another feature of the campaign which was of distinct value was the distribution by means of the rural free delivery of carefully prepared literature to those in the more remote rural districts and outlying farm areas who could not be reached by the lecture system. Copies of this literature were translated into French and distributed to the large French population in many communities.

In this way, through the efficiency of committees representing widely diversified groups of people, and the hearty co-operation of the medical profession of the State practically as a whole, a vastly greater number of people have had the vital facts about cancer placed before them than probably could have been done in any other way in a State of this kind.

One or more papers on the general subject of malignant disease have been read before each county medical society and a lecture or talk has been given to every nurse in training in every public and private hospital throughout the State, thus rounding out the proposed plan to reach every possible group of people.

This scheme was inaugurated and well under way before the National Cancer Week, it was intensified during this week, and it is proposed to carry it on without a let-up throughout the entire winter as was done last year. It is believed that a campaign of this order should be pushed with as much vigor and over as long a period as that against tuberculosis in order to accomplish the desired result, but it is quite evident that even the effort so far made has brought about small, but nevertheless very unmistakable, results as evidenced by the awakened interest in the subject shown by the medical profession throughout the State and by the increasing number of people seeking advice about conditions about which they are uncertain.

It is believed even further that the time has already arrived when efforts for prophylaxis against cancer should be systematically made, and it has been proposed by the chairman of the cancer control committee that "observation clinics" be established in the three larger hospitals of the State to which the profession can send doubtful cases for diagnosis, in which the inoperable case can receive proper x-ray or radium palliative treatment, and in which as large a number of patients as possible, especially women, shall be kept under observation

for a period of five to ten years in order to detect the possible early onset of malignancy or the treatment of definitely pre-cancerous conditions. Such a clinic can be run as an out-patient clinic and, if cases are properly catalogued and an adequate follow-up system instituted, there should be no difficulty in following cases and obtaining valuable results along the line of prophylaxis.

The health authorities of the State of Maine are trying to teach its people that the seeking of early advice from competent authorities in all matters of bodily abnormalities is the surest road to health and happiness and a long and useful life.

EDW. H. RISLEY, M.D.

Waterville, Me.

INFECTIOUS JAUNDICE.

New Haven, Conn., Nov. 24, 1922.

Mr. Editor:

The undersigned is desirous of obtaining information regarding the prevalence of Infectious Jaundice in your State.

The disease is non-reportable and information regarding its prevalence cannot therefore be obtained from Boards of Health.

I shall be grateful for any reports of outbreaks which your readers may care to send me.

GEORGE BLUMER, M.D.

[NOTE: In the interest of scientific medicine practitioners should unite with students of medical problems and forward information to those who are studying any form of disease. Massachusetts physicians should give all possible assistance to Dr. Blumer.—Editor.]

THE SCHOOL INSPECTION AND THE FAMILY PHYSICIAN.

Malden, November 24, 1922.

Mr. Editor:

With the development of school inspection we hear a good deal about the necessity of co-operation between the school medical personnel and the family physician which is, of course, highly desirable.

Unfortunately, my own experience in this regard has been very deplorable. I presume this was the experience of many practitioners. The school nurse very rarely, to say the least, takes the pains to find out whether the child supposed to be sick has a family physician and to get in touch with him. She usually undertakes to treat the patient herself or refer it to some charitable medical institution, no matter whether the patient is rich or poor.

With such an abnormal state of affairs, I think something must be done to correct this evil. No co-operation can exist between two parties when one is entirely ignored by the other.

Different medical societies ought to act upon it in their respective communities and see that this evil should be corrected.

Respectfully,

LOUIS SILVER.

THE ADDITION TO THE GARDNER STATE COLONY.

Mr. Editor:

Your letter of November 20 to the Department of Mental Diseases has been referred to me for reply.

This institution caring for the insane was developed and is developing with two ideas in mind: The Colony plan with fairly widely detached buildings, and occupation used as means of treatment. At the present moment 85% of our patients are occupied every day. During the early years of the institution cases were admitted only by transfer by the

Department of Mental Diseases, but for the past five years we have been a receiving hospital, receiving cases by voluntary application and by commitment from the community the same way as other state hospitals admit. Our census is now approximately 900, including those 50 in our family care system who are placed out in families.

The new hospital building now under construction is a fire-proof building, two stories and finished basement. The basement will provide an x-ray room, laboratory, dental room, dispensary, diet kitchen, continuous bath treatment room, lecture room for nurses, and various utility rooms. On the first floor are both single rooms and dormitories for medical and surgical cases for women. This provides for thirty-eight on this floor. There is also on this floor a suite for sick employees separate from the rest of the floor. On the second floor is an operating room, sterilizing room, ether and recovery room, observation room for nurses off the operating room. This floor will care for thirty-eight medical and surgical cases. Our consulting surgeon is A. F. Lowell, M. D., of Gardner, Mass. Plans for this building can be seen at the office of Curtis W. Bixby, Architect, 8 Beacon St., Boston, Mass.

We have also under construction this year, by our own labor, a new laundry building which will care for 1500 patients and employees. We are also constructing a subway to connect all of our main buildings, the total cost of which, when properly equipped, will be \$1600.

I am sending, under separate cover, a copy of our last annual report.

Very truly yours,

CHAS. E. THOMPSON,
Superintendent.

INTERNATIONAL CONVENTION OF INDIVIDUAL-PSYCHOLOGY.

Brooklyn, November 14, 1922.

Mr. Editor:

I have been authorized to inform you that an International Convention of Individual-Psychology will be held in Munich (Germany), on December 8, 9 and 10.

The program of the first day consists of a discussion of "Individual Psychology and a general outlook of the happenings in the world." (Individual-Psychologie und Weltanschauung.)

Then Dr. Alfred Adler of Vienna will deliver a very interesting lecture.

Also Professor Dr. D. E. Oppenheim of Vienna is going to speak of "Shakespeare's Knowledge of Human Nature."

Dr. Stumpf, Munich (Germany), Kaulbachstrasse 75/3, will be glad to answer any questions that anybody may have in regard to the convention and will make all reservations for those who plan to attend.

If you want further information about the Individual-Psychology I am in a position to obtain the work of one of America's famous professors on this subject.

I would thank you to take note of the above and remain,

Very truly yours,

(Signed) RICHARD KRAUSS,
c/o MR. ALEX. MARTINEK,
6813 4th Ave., Brooklyn, N. Y.

NEW ENGLAND DERMATOLOGICAL SOCIETY.

The regular quarterly meeting of the New England Dermatological Society will be held at the Boston City Hospital, in the Surgical Amphitheatre, on December 13, 1922, at three thirty p.m. All physicians who are interested are invited to attend.

HIC JACET.

In golden pre-Vesalian days
The barbers cut for stone,
And to the wondering yokels' gaze
A pebble (palmed) was shown.

Then simples, leaves, and herbs were brewed
And incantations spelled,
And by the force of magic rude
Black devils were expelled.

The ages with their noiseless tread
Moved silently along,
And some were purged and some were bled
Both copiously and long.

Then to the much enduring world
Came an enlightened day—
The bloody Moloch's flag was furled—
The cultists held their sway.

As water rushes from the spout
Our flood of knowledge grew,
And old ideas took hasty rout
Beleaguered by the new.

And still man's wisdom grew apace
As modern history shows—
Metallic tractors joined the race
And Mother Eddy rose.

Then maladjustments held the floor,
But there—enough's been said;
Why flaunt the vivid flag before
The angry Holstein's head?

Amid the fair Elysian fields
The gentle Coné roams;
To mild persuasion cancer yields;
Health broods above our homes.

Now Science truly has the laugh
On all that Hell can send,
For Father Abrams holds the staff—
And "Finis" can be penned.

Joe.

MORTALITY IN MASSACHUSETTS.

Mortality from the following causes in Massachusetts for the first six months of 1922, from statistics compiled by the Registrar of Vital Statistics:

Typhoid fever	25
Measles	101
Scarlet fever	103
Whooping cough	103
Diphtheria and croup	276
Influenza	487
Poliomyelitis	5
Tuberculosis of the lung	1740
All other forms of tuberculosis	313

(2053—105.2 annual rate per 100,000 population.)

Cancer	2334
(119.6 annual rate per 100,000 population.)	

Alcoholism	104
Meningitis	125
Cerebral hemorrhage	2305
Pericarditis, acute endocarditis and myocar-	
ditis, angina pectoris, other diseases of the	
heart	4741
(243.0 annual rate per 100,000 population.)	

Bronchopneumonia	2017
Pneumonia	1908
Diarrhea and enteritis (under two years)	321
Puerperal fever	91
Other puerperal affections	239
Congenital debility and malformations	1882
Violent deaths (excluding suicide, homicide, and	
automobile accidents)	958
Automobile accidents and injuries	198

Suicide	234
Homicide	50
These rates are based on an estimated population, 3,902,576, as of July 1, 1922.	

BOARD OF REGISTRATION IN MEDICINE.

EXAMINATION HELD SEPT. 12, 13, 14, 1922.

Applicants Examined	57

THE NATIONAL BOARD OF MEDICAL EXAMINERS announces the following dates for its next examinations: Part 1: February 12, 13 and 14, 1923. Part 11: February 15 and 16, 1923.

The fees for these examinations have been continued at the reduced rate for another year. Applications for these examinations must be forwarded not later than January 1, 1923. Application blanks and circulars of information may be obtained from the Secretary of the National Board, Dr. J. S. Rodman, Medical Arts Building, Philadelphia, Pa.

J. S. RODMAN, Secretary.

INSPECTOR, ANTINARCOTIC ACT. AGENT, ANTINARCOTIC ACT.

The United States Civil Service Commission announces open competitive examinations for the positions listed above. Receipt of applications to close December 31, 1922. Vacancies in the Internal Revenue Service of the Treasury Department, at the salaries indicated below, and in positions requiring similar qualifications, at these or higher or lower salaries, will be filled from these examinations, unless it is found in the interest of the service to fill any vacancy by restatement, transfer, or promotion.

The entrance salaries for both inspectors and agents will range from \$1,800 to \$2,250 a year (plus "bonuses"), with allowance for subsistence and actual necessary traveling expenses when away from post of duty on official business.

TRANSPORTATION TO SAN FRANCISCO NEXT JUNE.

The American Medical Association will hold its next annual session in San Francisco, June 25 to 30, 1923. Dr. Wendell C. Phillips, of 40 West 47th Street, New York, one of the trustees, is organizing a committee from the Eastern States to arrange for transportation to and from that meeting. He will be glad of the views of the Fellows of the Massachusetts Medical Society as to the sort of tours that would find most favor.

(Signed) Walter L. Burrage, Secretary.
November 27, 1922.

BOSTON CITY HOSPITAL. Staff Clinical Meeting, Cheever Surgical Amphitheatre, Thursday, December 14, 1922, at 8 P.M. Myocarditis, Francis W. Peabody; Mediastinal Tumors, Henry Jackson, Jr.; Spastic and Atonic Constipation, Percy B. Davidson, each discussion. Physicians and surgeons invited. Refreshments served 8:30 P.M. JOHN J. DOWLING, Superintendent.

SOCIETY MEETINGS. DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be continued from time to time, and will appear at each issue.

RECORDING DISTRICT. Hyannis.—February 2, 1923. (Annual Meeting) M. C. A. B. 1923.

Bristol South District.—Fall River.—May 3, 1923.

Essex North District.—Haverhill. (Semi-Annual Meeting)—January 8, 1923. Y. M. C. A. Building, Lawrence. (Annual Meeting)—May 2, 1923.

Essex South District. Medical Society meets Wednesday, December 13th, at Beverly Hospital, Beverly, 6 P.M. Speakers: Dr. W. P. Bowers, Managing Editor *Boston Medical and Surgical Journal*; Dr. John D. Adams, Boston; Dr. P. P. Johnson, Beverly. R. E. Stone, Secretary.

Suffolk District.—December 27, 1922; January 31, 1923; February 28, 1923; March 28, 1923; Annual Meeting, April 25, 1923.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexis Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, Dist. The date for each speaker has not been assigned.

Middlesex North District.—Meeting, Wednesday, January 31, 1923.

Middlesex East District.—Jan. 24, 1923. The Nursing Problem. Speaker to be announced later.

March 21, 1923. Mental Factors in Childhood. Paper by Dr. William Healy.

April 15, 1923. Interpretation of Laboratory Findings. Papers by Dr. E. G. Crabtree and one to be announced later.

May 9, 1923. Annual Meeting.

All meetings except the annual meeting will be held at the Harvard Club in Boston. A. E. Small, Secretary.

Worcester District Meetings are scheduled as follows:

December 13, 1922.—The meeting will be held in the G. A. R. Hall, Pearl Street. Programme: "Prostatectomy," Dr. J. D. Barney of Boston; "Anomalies of the Kidney," Dr. Walter D. Heberich; "A Series of Interesting Pyelograms in Genito-Urinary Lesions," Dr. Philip H. Cook.

January 10, 1923.—The meeting will be held at the Worcester State Hospital, Belmont Street, at 4:15 P.M. Programme: "A Discussion of Status Thymico-Lymphaticus and the Inherent Compensatory Possibilities," Dr. Walter Timmer, New York City. Discussion will be opened by Dr. W. A. Bryan.

February 14, 1923.—The meeting will be held at the Worcester City Hospital at 4:15 P.M. The programme will consist of a series of papers by members of the staff.

March 14, 1923.—The meeting will be held at St. Vincent's Hospital at 8:15 P.M. The programme will consist of a series of papers by members of the staff.

April 11, 1923.—The meeting will be held at Memorial Hospital at 8:15 P.M., and the programme will consist of a series of papers by members of the staff.

May 9, 1923.—Annual meeting and banquet.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

December, 1922.—New England Dermatological Society Meeting, Wednesday, December 13, 1922, at 3:30 P.M., in the Surgical Amphitheatre, Boston City Hospital; C. Guy Lane, Secretary.

December 20-30, 1922.—American Association for Advancement of Science meets in Boston.

December, 1922.—Boston Medical History Club will meet December 18, 1922.

January, 1923.—Massachusetts Society of Examining Physicians (date and place undecided); Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston; W. H. Allen, Mansfield, Mass., Secretary.

January, 1923.—Boston Association of Cardiac Clinics. Meeting January 18, 1923, at 8:15 P.M. Boston Lying-In Hospital (New Hospital). Subject: Pregnancy and Heart Disease.

January, 1923.—Boston Medical History Club will meet January 15, 1923.

February, 1923.—New England Dermatological Society Meeting, February 14, 1923, at 3:30 P.M., in the Skin Out-Patient Department, Massachusetts General Hospital; C. Guy Lane, Secretary.

February, 1923.—Boston Medical History Club will meet the third Monday of this month.

March, 1923.—Massachusetts Society of Examining Physicians (date and place undecided); Hilbert F. Day, Secretary.

March, 1923.—Boston Association of Cardiac Clinics. Meeting March 15, 1923, at 8:15 P.M. Boston City Hospital. Subject: Prevention of Heart Failure.

March, 1923.—Boston Medical History Club will meet the third Monday of this month.

April, 1923.—New England Dermatological Society Meeting, April 11, 1923, at 3:30 P.M., in the Surgical Amphitheatre, Boston City Hospital; C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston; W. H. Allen, Mansfield, Mass., Secretary.

April, 1923.—Boston Medical History Club will meet the third Monday of this month.

May, 1923.—Massachusetts Society of Examining Physicians (date and place undecided). American Pediatric Society Meeting, May 31, June 1 and 2, 1923, at French Lick Springs Hotel, French Lick, Ind.; H. C. Carpenter, Secretary.

May, 1923.—Boston Association of Cardiac Clinics. Meeting May 17, 1923, at 8:15 P.M. Children's Hospital. Subject: Rheumatism and Chorea and Heart Disease.

June, 1923.—American Medical Association, San Francisco, June 25-29, 1923; Alexander R. Craig, Chicago, Ill., Secretary.

July, 1923.—Massachusetts Association of Boards of Health, July 26, Nantasket; W. H. Allen, Mansfield, Mass., Secretary.

THE MENTAL HYGIENE CAMPAIGN AS SEEN BY AN OUTSIDE OBSERVER.

BY BRONSON CROTHERS, M.D., BOSTON.

THE National Committee for Mental Hygiene is conducting a campaign which should arouse the active interest of the whole medical profession. The enormous importance of the problems involved has been brought home to a considerable portion of the public, whose interest was shown in crowded meetings during the most inclement part of last winter. Doctors are not entitled to an attitude of detached interest or of indifferent acquiescence. A public health movement of great importance is under way and it is the plain duty of physicians to formulate a definite opinion.

The evidence upon which such an opinion can be based is readily available. The Committee has published for about six years a quarterly magazine, *Mental Hygiene*, in which original articles are supplemented by admirable reviews and abstracts. With the files of this journal as a starting point it is possible to select essential collateral reading without going too deeply into technical psychiatric and psychologic literature.

Any attempt to record the result of such a survey of the Mental Hygiene movement as a

collective abstract would be sterile, as the fields covered include practically every activity of human life. It is an interesting exercise, however, to attempt to formulate an individual reaction to such a series of fascinating stimuli. Naturally such a method of review is open to all sorts of objections. Of course, the result represents merely a point of view, dependent on prejudice, selection and various other unscientific foundations, but it has certain merits, which the more conventional collective abstract cannot have.

The challenge to the medical profession is a definite one. Some of the psychiatric and psychologic leaders feel that a very large percentage of all mental disorders, by one speaker placed at 50%, are preventable by technique now available. The tremendous burden of deficiency, delinquency and insanity is hardly realized except by special students of the problem. If physicians are neglecting opportunities for effective treatment, they are thoroughly blameworthy if they do not at once make sure that those influenced by them understand the new possibilities. However, before acknowledging error it is only sensible to subject the whole matter to careful examination.

The active work of the National Committee is obviously under the control of psychiatrists and psychologists. Further, it is clear that these men represent the best in their fields. Quite naturally, some of them appear not to encour-

age other groups to share the responsibility of leadership. This distrust of other people is clearly formulated in several articles. When leadership in a movement is so limited and so jealously guarded it is entirely proper to search for reasons.

Obviously if Mental Hygiene is a pure science the control must rest with the originators and the practitioners of the science. That it is a distinct science is stated by Dr. L. F. Barker in the Presidential address at the tenth anniversary of the Committee. Under such circumstances it is open to the rest of us to take it or leave it, but it is impertinent to try to break into any active participation in its direction, unless we are asked.

But apparently there is no general agreement that Mental Hygiene is a separate and pure science. Many active members of the Committee regard it rather as an attempt to co-ordinate every effort being made for better mental life. Under such a definition every one of us who is interested in education, religion, politics or medicine, is, according to our lights, a mental hygienist. From this point of view we have rights in the selection of leaders. If the psychiatrists and the psychologists as a class show themselves wiser and more resourceful in dealing with the problems of the human mind than other men, we may look to them as chosen and not as self-appointed leaders.

As far as I am concerned, I cannot take seriously Mental Hygiene as a new science and I shall consider it as an attempt at correlating all the various activities aiming at better conditions and at formulating a plan of action.

From this point of view I at once admit the validity of the psychiatric and psychologic claim to leadership in the treatment and diagnosis of recognized mental disturbance, including deficiency, delinquency and insanity as well as disabling or disturbing neuroses. When I accept this limited leadership it means that I will use what influence I have in support of provision of such diagnostic clinics as may be needed, such psychologic studies as may help in the recognition of feeble-minded in the schools, and whatever psychologic or psychiatric investigation may be of help to the courts. Moreover, as a natural consequence of this attitude, I will try to study patients in such a way as to recognize psychiatric problems. Naturally recognition will lead to efforts at logical treatment or reference to experts in psychiatry or psychology.

However, the literature under review contains much that shows that certain mental hygienists aim at far more than the detection and treatment of mental disorders. Some of them go so far as to include common sense and normal in the quotation marks of doubt and decision. To these gentlemen the field of activity is broadened to include us all. Naturally

they view children as the rough material from which neurotic and badly adjusted adults will develop.

As I see it, the non-psychiatric doctor regards the psychiatrist as a specialist in insanity and the psychologist as an academic seeker after rather obscure data. Such an attitude is entirely unnecessary, but the fault lies with some of the experts as much as with the rest of us. As long as this attitude is maintained everybody will be working at cross purposes.

For my own part, I have got a good deal of satisfaction from a working classification which fits most of the experts of my acquaintance.

By far the biggest group are broad-minded, hard-working people who talk reasonably about the problems that interest them. Their methods are perfectly logical and they claim no immunity from criticism. Naturally such people are able to study personality with great benefit. Where the worst of us dismiss a "nervous child" with routine advice as to rest and discipline and give the mother a prescription for nux vomica and bromides, the wise psychiatrist settles down with every one concerned. His essential technic consists of stimulating listening. He does not "take a history" from the mother, but he finds out what influences have acted on the child, what sort of interests he has, how he plays, what he does in off hours, how he gets along in school. He also, as a part of his study of the child, gets a clear idea of the whole family, the school teacher and the nurse. Much of this information is obtained by carefully trained social workers. The physical examination and perhaps a formal psychological test rule out certain defects.

Then, on the basis of this careful, painstaking procedure he suggests and supervises a course of action. The patient is taught to take an active part in his own cure, instead of being regulated and drugged. Naturally the result depends, largely, on the wisdom of the psychiatrist. On the face of it it is clear that no one capable of utilizing a method so time-consuming is likely to lack patience and he is almost certain to possess wisdom.

Another group, on the whole, I think, less efficient, shut themselves up with their patients and work along purely Freudian lines. The procedure is far more obscure and discussion is curiously difficult. If Dr. Freud and his disciples had not succeeded in making best sellers of medical text books, there would be little to justify amateur discussion of a highly complicated technical procedure. However, I feel that Freudians as mental hygienists have a claim to separate consideration.

A third group, whose procedure is simplicity itself, have assumed a rôle of great prominence. The more extreme advocates of Binet-Simon tests have a conception of life which seems to

me grotesque. If the mental testers of this type really represented psychology I should be entirely willing to get on without psychology, for reasons to be given. The claim to immunity from outside criticism practically eliminates their method from consideration as a part of true mental hygiene. This view is apparently backed up by most psychiatrists and many psychologists who regard intelligence tests as of limited value in certain fields. I shall discuss only the extreme advocates of "mental age." The rest of the psychologists range from them to quiet and useful students.

A fourth nondescript group includes a certain number of scientists whose interests only casually touch clinical medicine or mental hygiene and a large number of enthusiasts who use methods with more than a little suggestion of the occult.

As far as the National Committee is concerned, the strength of the movement lies in the predominance of the sane, vigorous students of human nature who are quite competent to handle the various complicated technical methods of modern psychiatry and psychology. The weakness, if there is any, is the enthusiasm of certain men who are so fascinated by technique that they are willing to attempt to popularize technical methods, which, taken from their place as details of procedure in a wise and patient investigation by experts, are subject to serious misuse. When a speaker suggests that 50% of mental disease is preventable by early attention to "conflicts" the listener may well inspect his evidence and examine his credentials.

Under guidance of the best, what may we expect from Mental Hygiene? In answer, the propagandists point to the anti-tuberculosis movement as an example. This analogy deserves more than casual attention.

The present programme of the various anti-tuberculosis agencies is a perfectly definite one. In the first place the disease, however protean its pathology, is due to a single group of organisms.

The prevention of tuberculosis depends on avoidance of infection or on developing or maintaining resistance. The signs of the disease are recognized, on proper examination, while the malady is still curable. The means of treatment are, to a large degree, well understood.

The leadership of experts is accepted because all of us are able to understand the methods by which they come to conclusions, even though we may be ignorant of details of bacteriology or pathology. Many of the bits of technique are carried out by the State or under its supervision. Some of the methods have received the sanction of the law and are enforced by the police.

When we compare this well formulated cam-

paign with the problems confronted by the mental hygienists we see more points of difference than of likeness. For mental disorders may be the result of infection with any one of a number of organisms, of dissatisfaction with environment, of heredity, of accident or of endocrine disturbances—to mention only a few causes.

The prevention of disorders of the mind obviously involves the coöperation of every agency interested in human welfare.

The task of finding a starting point is a hard one. Various methods are possible. The mental expert can focus his attention on recognized mental disorders and try to educate people to regard these disorders as curable diseases, not as disgraces. As soon as this point of view is accepted, earlier diagnosis of psychoses and deficiency, with adequate care for less advanced sufferers, would naturally follow. Or he can approach the subject in a different way and lay stress on the fact that most preventable mental diseases begin in childhood. From this point of view he will regard preventive psychiatry as education in its broadest sense. Obviously he can combine both points of view, but, if he does so, he leaves himself open to challenges as a leader of education, to which, as a therapist, he is not liable.

The present campaign involves all these aspects. The psychiatrists and psychologists who direct the work of the National Committee for Mental Hygiene have challenged not only our methods of dealing with disordered minds but our methods of bringing up children.

Such a challenge can be considered only in sections. I believe it is entirely fair to eliminate any discussion of the treatment of developed disorders of the mind from discussion, not because it is not important, but because I yield absolutely to the authority of experts in these matters.

When it comes to acknowledging the right of these experts to supervision of the life of "normal" children (the quotation marks are the psychiatrist's), I do not feel so diffident.

Parents see more of individual children than any psychiatrist who is not also a parent. Teachers, pediatricians, scout masters, and any number of others see more children than any psychiatrist. On the face of it, the knowledge of children's minds is not confined to any one group.

The wise psychiatrist or psychologist can obviously help a lot. There is no valid reason for supposing that he sets himself up as more than a competent adviser on certain problems of childhood. The trouble is that a few do claim precedence over teachers and other veterans.

The first group of extremists are followers of Sigmund Freud. Over and over, these men denounce almost everyone else as mediaeval and incompetent. They are now trying to popu-

larize Freudian technic. Whatever else they do, they must be causing great agitation at the headquarters of the Committee. Certainly they are causing a variety of emotions among the rest of us. On the whole they add enormously to the gaiety of life as they discuss with pompous and astonishing vocabulary every subject from humor to Lady Macbeth. As the *enfants terribles* of Mental Hygiene they have a striking rôle.

The dilemma in which the Freudian finds himself is an interesting and difficult one. If he confines his efforts to individuals and uses the Freudian technic to help those seeking his personal assistance, he limits his field enormously. A very few patients will absorb all his time and energy. On the other hand, if he attempts to spread the ideas formulated by Freud he lays himself open to most serious dangers.

In order to understand Freud one must study with great attention a most complicated series of theories. Every Freudian warns the novice that misinterpretation at the start is to be expected. In fact, the initial refractory stage, otherwise, I believe, known as "resistance," is one of the strongest arguments for the truth of the theory. Between doctor and patient this resistance can be overcome, but it often takes time. In every case it requires considerable personal study before complete confidence allows utter frankness. The quality of this frankness astonishes almost everyone. It is literally absolute.

The mental hygienist cannot possibly reach the large audience which must be influenced if propaganda is to be effective, by any such methods. Certain writers and speakers, therefore, have attempted a formidable task. They apparently guess at the probable average "resistance" of their audience, and temper their frankness to it. The result appears to be bizarre. The only effect on a certain number is intellectual disgust. Naturally the group who react in this way include many who need help tremendously. They tend to dismiss mental hygiene without a blessing. Another group learn that words, hitherto spurned as obscene, are entirely scientific. This fascinating discovery leads to an absurd misinterpretation of an important technic, as well as to injudicious and persistent conversation of a highly objectionable type. Here and there, doubtless, a student may be urged to follow the difficult road to real understanding.

Such an interpretation may be entirely unfair, but for the last two years I have tried with great earnestness to find a medical student or a layman, not specializing in psychology or psychiatry, who had a working knowledge of the difference between repression and discipline, between fantasy and imagination, between libido and ambition, or between erotism and sensuality.

This general failure to understand a philosophy as difficult as that under discussion seems to me to show that efforts to propagate it by elementary discussions are quite futile. In the mothers of children, half-knowledge of this sort has led, in many cases, to complete lack of faith in everyone having to do with the child.

Certain books which seem to me in the highest degree unfortunate have been published. The entirely false impression they create is obvious. For example, a few years ago von Hug-Hellmuth's "Mental Life of the Child" appeared with an appreciative foreword by its translator, one of the most admirable medical philosophers of the time. Later on this volume was reviewed, with some misgivings, but with considerable approval, in *Mental Hygiene*. I quite realize the unfairness of picking out details, but when within the first few pages one finds that the new-born baby scratches itself, showing masochism, scratches its grandmother, showing sadistic trends of thought, and later enjoys sucking its finger because the smell of the softened skin has an odor suggesting the genitals, it is hard to read dispassionately. For one thing, Sherrington showed us, long ago, far more sadistic or masochistic trends in spinal dogs, who can hardly be supposed to harbor erotic ideas, and Head and Riddoch demonstrated undoubted sexual reflexes in men with complete transections of the spinal cord. Yet reviewers regard this book as valuable, though they naïvely suggest that readers should be able to discount the overemphasis in sex.

More popular volumes written by important and active members of the Committee are full of auto-erotism, mother-complexes and the rest of the Freudian vocabulary.

Without presuming to express any opinion on Freudian technic in its therapeutic aspect, I do feel that it is proper to express a deep distrust for any popular movement which attempts to spread its principles among laymen. For one thing, as far as I know, it is not accompanied by any well-formulated plan for teaching sex hygiene. Without rational sex teaching the emphasis on sex must, I believe, be disturbing without being helpful.

Another conspicuous recent contribution to mental science is the standardized psychological test of intelligence. After wandering for months in the confused fields of Freudian philosophy, conscious all the time that if I only understood I could probably get a flood of light, and feeling restless at being unable to follow language which apparently was plain English, it was delightfully refreshing to get on firm ground again. The problems of human existence were, after all, quite simple. A standard textbook on psychological tests gives the following summary of most of life's problems in terms of intelligence:

"Morality depends on two things: (a) the

ability to foresee and to weigh the possible consequences for self and others of different kinds of behavior; and (b) upon the willingness and capacity to exercise self-restraint. That there are many intelligent criminals is due to the fact that (a) may exist without (b). On the other hand, (b) presupposes (a). In other words, not all criminals are feeble-minded, but all feeble-minded are at least potential criminals. That every feeble-minded woman is a potential prostitute would hardly be denied by anyone. Moral judgment, like business judgment, social judgment, or any other kind of higher thought process, is a function of intelligence."

Having formulated an almost too simple explanation of ethics the author goes on to his methods of classifying intelligence: "The standardized tests have already become and will remain by far the most reliable single method for grading intelligence," and "without question the improved Binet tests will contribute more than all other data combined to the end of enabling us to forecast a child's possibility of future improvement, and this is the information which will aid most in the proper direction of his education."

To be sure, the author makes a few half-hearted reservations, but it is impossible for me to believe that he does not feel that the solution of the problems of life are largely dependent on the Binet-tested intelligence of the American people. However, in one of the dogmatic perorations which make his introductory chapters read like a book of directions on salesmanship, he says: "Binet testing is destined to become universally known and practiced in schools, prisons, reformatories, charity stations, orphan asylums, and even ordinary homes, for the same reason that Babcock testing has become universal in dairying. Each is indispensable to its purpose."

This is a statement I can agree to without much reservation. I know just enough about dairying to understand the value of the Babcock test. This test measures butter fat; it is, therefore, an accurate measure of the commercial value of the milk to the butter-maker, but it bears almost no relation to the value of the milk for other purposes. In fact, no wide-awake Board of Health would admit to sale any milk on the basis of fat content alone. Bacterial counts, methods of distribution and methods of preparation count for vastly more.

I agree that, for the present, the improved Binet test is a very useful short cut to knowledge of intelligence, but that it will keep its position seems, on general principles, uncertain, and that intelligence has any such vital relation to behavior, as is suggested, I doubt. Not that this opinion is of any interest to the author quoted, for he discounts it in advance. He says: "Criticisms of the Binet method have also been frequently voiced, but chiefly by persons who

have had little experience with it, or by those whose scientific training hardly justifies an opinion. It cannot be too strongly emphasized that eminence in law, medicine, education or any other profession does not of itself enable anyone to pass judgment on the validity of a psychological method."

Under such circumstances I prefer to leave the Binet test where its champion has put it: with the Babcock test. At least no dairyman has challenged the right of doctors to judge medical values in his business, and if he did the law tends to recognize the medical opinion.

The quotations are not from a member of the National Committee, but they show a point of view which is too prevalent.

The term "mental age, in my opinion, is exasperating, and it is used over and over in the mental hygiene literature. The words "mental age" really mean the figure obtained by the Binet test or by some comparable procedure. Before I should be willing to listen seriously to any psychologist as a mental hygienist, I should demand proof that he used some other words. All that the psychologist has a right to mean by mental age is a more or less incomplete judgment of the level of intelligence. If, in his opinion, "intelligence" covers "mind," we ought to know it: if it does not, he is guilty of extraordinary looseness in the use of language—which, I believe, makes him a dangerous propagandist.

Most of the mental hygienists have serious doubts about the validity of the extreme psychological point of view. For instance, Dr. W. A. White, an important member of the National Committee, uses the following words in concluding a plea for a more or less Freudian conception of mental hygiene: "I am minded at this point to compare with the broad behavioristic program that I have indicated, the restricted scheme that is spanned only too often by the Binet-Simon scale. This scale, as devised by its originator, may be a very valuable tool in the hands of a skilled observer, but as the 'be-all and end-all' of child psychology it may become quite as vicious in its results as the fatalism inspired by the false theories of heredity I have already mentioned."

Abundant testimony from psychologists is also available to contradict the conclusions arrived at by the author first quoted. My point is, not that most psychologists are fools, but that we must bear constantly in mind that they are pioneers and enthusiasts. The virtues of the effective pioneer rarely include reticence or understatement. Quite unconsciously the joy of discovery often forces announcement before the finders know exactly what they have found.

At present psychologists are constantly finding new methods. I can see no possible reason for believing that they are in a position to force their adoption. They are a vigorous, stimulating group, but they have no claim to immunity

from criticism. Certainly they criticise each other.

In addition to Freudianism and psychological testing there is a considerable literature on endocrinology, syphilis, heredity and so on. On these subjects doctors can be assumed to possess capacity for adequate judgment.

The followers of Freud and the extreme psychologic testers demand, first, unbounded respect for their knowledge, without criticism by those outside the fold, and second, loyal support of a program based on this respect. Support on any such basis is not demanded as far as I know by any other scientific men. It involves an element of faith, not really arguable. When an engineer presents plans for a bridge to taxpayers his plans are accepted and carried to completion, not because we know anything about the calculations of stresses, etc., but because we feel that if we cared to go into the matter we could check his calculations. In no other way, I believe, can continuous support be obtained, without calling on faith. When the Freudian regards vigorous antagonism as a proof of the validity of his views or the psychologist asserts his immunity to criticism, neither has any logical right to resent lack of interest or flat hostility.

The best of the mental hygienists see this clearly enough. On the whole they base their claim to attention on far more reasonable grounds. They study problems in a thoroughly admirable way. The wisdom and patience of such people as Dr. Healy in Juvenile Court work and Dr. Esther Richards in school and hospital, to mention only examples, show the tremendous amount of solid work that is being done. In neither of these people is there the least trace of blind devotion to technic. On the other hand, it is quite clear that the assets of the ideal mental hygienist consist of patience and wisdom to an almost abnormal degree. If the mental hygiene committee will guarantee a steady supply of such people the rest of us can leave details in their hands. If they propose to impose upon us lecturers on Freud and Binet testers we may well test their personnel, not by laboratory methods, but by such tests as will convince us of their wisdom and common sense.

My own belief is that mental hygiene by highly specialized technic is an inconceivable thing, on any large scale, because I see no reason to suppose that a sufficient number of wise and patient people will devote their lives to psychiatry or psychology to control elaborate technic reasonably.

At this point it is of interest to quote Dr. Adolph Meyer, one of the true leaders of rational mental hygiene. In a presidential address to the American Neurological Association he said: "There may be a few among us who feel that neurology should maintain its exclusive and dominant attitude by pointing to its limits as an extraneous and practically

negligible asylum and sanatorium field, and that what can be handled at large should be handled under a vernacular of general medical and neurologic camouflage, sparing the public's feeling about the mind. Neither the conscience of the profession nor the state of public opinion can drift profitably in this manner. The most practicable step towards the solution of our problem is the rounding off of our training among ourselves and in our general medical curriculums by giving the student and worker good foundations for the simple and everyday tasks of psychology and understanding of ordinary personalities and their problems and needs. Let us realize among ourselves that neuropsychiatry stands for making organized and critical medicine a field of work with personalities as well as with part organs and functions, and that while there must be special workers devoted to special research in the special fields, no physician and no intelligent lay person can afford to disregard the gains by the modern readjustment; the recognition of life problems on the psycho-biologic level of integration, the promotion of a training in medicine dealing with the defective and unusual child, the growth of interest in the minor difficulties of human behavior and mentation and the humanizing of the work with all states and conditions of disease and mal-adaptation."

Dr. Meyer uses technical words, but a very few hours of reading allows anyone to understand exactly what they mean. He claims leadership, as an acknowledged expert, but he invites interest and discussion. Whether or not we follow him depends on our good sense and our industry. In any case he offers us a clear opportunity for sharing his information and learning his methods without giving up other lines of medical activity. Leadership of this type we can all accept.

The conclusions to be drawn from a review of such varied reading matter cannot be very definite. It is quite obvious that the irritating parts of the programme have demanded an undue portion of attention. However, this much can be stated,—

Mental hygiene, as discussed in authoritative literature, can be divided into two parts. In one are included plans for the earlier diagnosis and proper treatment of mental disorders. The authority of psychiatrists and psychologists to lead physicians in this part of mental hygiene is unquestioned and vigorous coöperation is properly asked.

The preventive side of the work concerns education, in its broadest sense. The upbringing of the next generation is not a matter for specialists alone. Teachers, clergymen, doctors and social workers act as advisers to parents, or act, under proper authority, as their deputies.

The danger, I believe, lies in mixing up these two parts of the programme. One is definite

and demands active support, the other is tentative and demands discussion.

The therapeutic side should be strictly supervised by experts. The preventive side can properly be discussed by anyone who cares to argue.

The weakness of the attitude of some mental hygienists, notably of the extremists among Freudians and mental testers, lies in a perfectly illogical demand for active support based on uncritical acceptance of disputed theories.

The duty of physicians seems to me plain. Mental hygiene is no revelation, it is open to intelligent criticism. Too many laymen regard it as a new faith. As physicians we should watch sympathetically, but critically, and we should guard against the well recognized dangers of enthusiastic and misguided lay application of medical methods.

Fortunately the National Committee has furnished, in accessible form, the literature which needs to be consulted. The examination of this evidence is interesting, profitable and easy. That some of it arouses discussion is inevitable. The National Committee, as a whole, should welcome professional interest. If doctors do not show interest it will be their own fault if they find that charlatans and unscrupulous enthusiasts are capitalizing the interest which the National Committee has aroused.

ILLUSTRATIONS OF DIFFERENTIAL DIAGNOSIS OF SOME TORPID STATES: THE THERAPEUTIC IMPORT.

BY TOM A. WILLIAMS, M.B., C.M., WASHINGTON, D. C.

Corresponding Member of the Neurological Society of Paris and of the National Academy of Medicine of Rio de Janeiro, etc.

THE obtuseness of consciousness is one of the earliest and most alarming phenomena which attracted the attention of students of disease. This is not the place for historical survey of the views regarding consciousness or its loss. For this presentation is to be confined to some aspects of differential diagnosis of some of the causes of impairment of consciousness. It is merely a survey of a few cases the superficial resemblance of which made the differential diagnosis all the more important.

CASE 1.—The first patient was a man of 22, seen at Spartanburg, with Dr. Fike. Three weeks previously he had suddenly occurred a feeling of stress in the eyes as if congested, and this was followed by an excited delirium. From this he had passed into a state of torpor. When I saw him this was less evident, but there was still some clouding of consciousness and slowing of responses and movement, and inability to understand unless remarks were quite simple.

However, physical examination showed absence of left achilles reflex, diminution of the right adductor reflex, a weakness of right internal rectus, an impaired diadochokinesis, slight

jerky tremor in movement, a dull facies, and wide and sluggish pupils. These signs, in conjunction with the rapid onset, the delirium, and the torpidity, pointed to encephalitis as the possible diagnosis. This opinion was confirmed by the further progress of the case, the patient markedly improving.

This case must be contrasted with the young man now presented.

CASE 2.—Here one notes the bent attitude, stooped shoulders, with the head poked forward with a set and staring look, the shortness of the steps in walking, the lack of briskness of movement. Palpation discovers a rigidity of the limbs, trunk, and neck, and the patient complains of pain of the muscles above the shoulder. This state is the sequel of an encephalitis which had been diagnosed as influenza some two years ago, in spite of the extreme lassitude and torpidity of the patient during the attack.

A number of cases of this kind are now being seen by neurologists. In some of them tremor is a marked feature. They present the syndrome produced by lesions in the region of the corpus striatum. Some physiologists believe that in this region the injury falls upon a system which governs the muscle tone, lesions of which produce both rigidity and tremor without preventing voluntary movement, which, however, becomes impaired on account of excess of muscular tension.

The resemblance of this syndrome to Parkinson's disease is very striking. The differential diagnosis is made by the onset of the former occurring after an acute illness, encephalitis, and by its comparatively rapid onset within a few months, while Parkinson's disease comes on insidiously during a period of years. Also, it is very rare except during the decline of life, whereas postencephalitic dystonia may occur before the prime of life, as in this case.

Much misconception has occurred from the use of the name "lethargic," as torpidity is by no means constant in encephalitis. Restlessness, on the contrary, almost always occurs, although it may not show itself for months. Wakefulness may be the predominant symptom and may last for months. Oculomotor paralysis may be absent even though the disease is a diffuse one. The frequency of its occurrence is due to the concentration of the oculomotor cells in nuclei and to the delicacy of their functions, the impairment of which is easily detected. On the contrary, a lesion of equal severity in the centrum ovale may show no focal signs. In some cases the functions are well performed until months after the development of the disease, when a Parkinsonian syndrome may appear, as in the foregoing case.

In the extremely torpid cases, catalepsy may occur, and in that case there may be a temptation to diagnose catatonic dementia precox. Careful neurological study should prevent this error, which the future course of the case will, however, rectify.

One has to differentiate encephalitis from such a case as the following:

CASE 3.—A man of 41 was seen with Dr. Steedly, also at Spartanburg. Four months before he had had an apoplectic attack, blood pressure 198, followed by torpor, headache in the left temple, aphasia, and weakness of the right side. In hospital the blood pressure fell to 140, and he improved, but relapsed three months later, with periods of semiconsciousness. Examination showed an extensor response of the right plantar reflex, absent right abdominal, diminished cremasterics, a weak grip of the right hand, diadochokinesis impaired on both sides, perseveration of movement, possibly some apraxia, substitutory aphasia and poor comprehension, though automatic speech was better than responsive speech, and neither showed dysarthria. The Wassermann reaction was negative and the spinal fluid contained 10 cells per cubic millimeter. There had been strabismus, and there was slight diplopia, but not hemianopsia. The visual fields were not examined at the time. Nothing abnormal could be seen in the optic disks and there was no pupillary deficiency. There was slight facial asymmetry. The most significant feature of the case was that on sitting up there occurred excruciating pain in the left temple, dizziness, and an aggravation of the speech defect. The man, in every way, except in his nervous system, was in the best of health, with a blood pressure never exceeding 140.

In so powerful a man, free of renal disease and hypertension, one had to reject the earlier diagnosis of apoplexy. The severity of the relapse and the lateralization of the physical signs were against a diagnosis of encephalitis in spite of the suddenness of the attack. On account of the one-sidedness of the signs, and their severity, the aphasia, the hemiplegia, the perseveration, and, above all, the localization of a headache, though aggravated by change of posture, the diagnosis made was a neoplasm of the left frontal lobe.

CASE 4.—Another variety of torpidity is exemplified in a woman of 45, seen near Rutherfordton, N. C., because of a coma with delirium which had occurred two weeks after a febrile attack with pain in the chest. She had lost appetite for a considerable time and had been severely constipated and had emaciated greatly. Examination found equal reflexes, reacting pupils, normal sensibility, dragging movements, and a lucid though very sluggish mind. The skin was rough and dry, and there was a bristly eruption on the back of the wrists; the tongue was scarcely red, but on inquiry the family doctor said he had remarked its extreme redness two weeks before. Inquiry showed that there had been a great lack of variety in her food for the preceding six months; it consisting almost entirely of grits and molasses, as she did not care for meat, and green vegetables were almost unobtainable. The absence of neurological signs in a case of acute onset, and the quality of the torpidity, quite unlike that seen in encephalitis, caused a rejection of that diagnosis, while the red tongue, the rapid emaciation, the eruption on the wrists and the history of dietary deficiency led to the diagnosis of pellagra, in spite of the absence of diarrhea.

CONFUSION FROM TOXICOSIS.

CASE 5. *Post-Influenzal Confusion with Eclamps.* In May, 1915, a judge, aged 61, after a severe attack of influenza, remained very weak, confused in mind, and began to develop hallucinations and delusions of a vague character. Several consultants were seen without result, and he became weaker and less clear mentally. The patient was in a typical condition of mental confusion. Deep reflexes were

very faint, abdominal reflexes were absent, there was plantar flexion. There was no paralysis and no anesthesia, so far as could be ascertained. The optic disk was not edematous and showed no arteriosclerosis, but the superficial vessels had thickened coats, though the heart was small, the apex reaching only to the lower border of the fourth rib, one inch inside the nipple line. Systolic blood pressure was 102, the diastolic 60. The kidney function had been ascertained by Dr. A. Hogue to be normal, phthalin appearing in ten minutes, to the amount of 30 per cent, and 34 per cent in the first and second hour, respectively. But there was a large quantity of indican and a slight trace of albumin.

The patient was taking the following diet and medication: 2 A. M., beef juice; 3:30, ammonia; 4, red solution potassium iodide; 5:30, grapefruit juice; 6:15, three tablets, egg, whiskey, milk; 7:30, ten drops adrenalin solution; 8, ten drops solution iodide of potassium; 10:20, soft toast, coffee; 11:15, three tablets—caffeine, strychnine, spartein; 12, ten drops B. P.; 12:30, ten drops solution; 1:30, beef tea; 2:30, ammonia; 3:30, three tablets; 4, custard, cream; 4:30, ten drops B. P.; 4:45, ammonia; 5, ten drops solution; 7, egg, whiskey, milk.

I consider this a case of acute exhaustion psychosis, partly toxic in character. The treatment prescribed was embodied in the following report to his physician:

As the patient is suffering from exhaustion, stimulants are contraindicated as the tired organ is incapable of further response to them; therefore, I think it wise to omit caffeine, the secondary effects of which increase the exhaustion.

Strychnine should not be further given either; for it merely increases the discharge that is the exhaustion of energy of medullary neurones.

Sparteine is a nerve-muscle poison, the effect of which in improving cardiac activity cannot be maintained for long without greater nutritional capacity by this patient.

It is true that an occasional case of paresis very rarely has as low a lymphocytosis; but never during an acute attack of the period simulated by this patient.

I see no advantage in the iodide of potassium. Furthermore, the basic element of this is a strong cardiac depressant. Nor should I give the bromides during the effort to build up the patient, as they diminish metabolic processes and diminish resistance. Ammonia should be kept for emergencies only, as its effect is evanescent.

The régime I prescribe is as follows: 6 A.M., five grains of sodium bicarbonate in four ounces of hot water; 6:15, one orange; 6:30 breakfast, cereal and milk, one egg, crisp bacon; 8:30, massage, consisting of slow, deep pressure without friction; the purpose of this is to increase the *vis a tergo* of the circulation and thus aid the heart by saving its *vis a fronte*. Sleep if possible.

On waking, about 9:30, five grains sodium bicarbonate in four ounces of water; 10 to 10:30, lunch—one banana, cereal, and milk; 12 to 12:30, massage, sleep; 2 to 2:30, dinner, meat and potatoes, green vegetables; 4:30, massage, followed

by five grains sodium bicarbonate in four ounces water; 6.30, supper—unpolished rice and milk, one banana. Between that and midnight, massage again when the patient is awake. For midnight lunch, Graham crackers and milk are desirable. The quantity of milk at one meal should not exceed five ounces. After meals the patient should be given one capsule of "phytin," an organic phosphorus preparation of the Society of Chemical Industry of Basle.

Beef-tea and gelatin should be omitted as containing too much excrementitious materials, which are cardiac poisons. Coffee and tea should be omitted also. A small piece of bread, with or without butter, may be taken with each meal if desired. Water should be the drink, and should be given about one hour before each meal, but should not be restricted to that time if the patient desires it at any other.

The adrenal principle should be continued; and I think it is better given as the dried gland, say three tablets a day to start with. I think that its effect might be improved by being taken along with 1 tabloid of "hormotone."

If this diet is found to be too heavy, diminish the quantities at the commencement. If the patient suffers from the heat, cool sponging should be beneficial; and in any case its effect upon the innervation of the vascular system is usually most beneficial; the water should be used lukewarm. The best cereals to give are puffed grains, with an occasional change to oatmeal and the brown prepared wheats, such as Ralston's. If the patient should desire any one article of food, let him have it occasionally.

When these measures were carried out, improvement was rapid; so that in four weeks the patient was able to be about, and the following term took his place on the bench, and remains well at this time, seven years later.

CASE 6.—Marked Confusion Due to Metabolic Migraine Resembling Petit Mal.—A bacteriologist, aged thirty, was referred to the writer in the spring of 1912, because of attacks he called "bilious" (but not preceded or accompanied by constipation), which produced headache, preceded by numbness and pricking in the fingers, followed by dizziness, mental confusion, and foolish talk of paraphasic type, without loss of consciousness. These attacks had occurred every two or three months since the age of twenty-two; they were of short duration; there were no scotomata, but they were formerly accompanied by vomiting. The headache was of the splitting kind, lasted all day, and was followed by dullness and slowness of thought the day following. The capacity to concentrate his thoughts was increasingly impaired even between the attacks. He was at times irritable. He had no bad habits, and apart from these attacks he was well and strong. He received a blow on the side of the head when a boy, and there was still a dent in the left parietal region, upon which side the headache most often occurred. He had a large appetite, which he said he controlled, but he ate meat thrice a day, although, he said, sparingly. The blood pressure was not raised, and reflexes and sensibility were normal.

Treatment and Progress.—He was given the "low-protein standard" diet. He wrote me the following winter: "Since I have reduced the amount of protein in my diet and increased the quantity of

vegetables, I have had no recurrence of these spells." His physician informed me that he remained well over three years later.

ENDOCRINE TYPES OF TORPIDITY.

CASE 7.—Hypoadrenia.—Some years ago a mechanic of 18 was seen with Dr. W. Carr, Jr. He was quite unable to work, because of extreme depression, slowness of thinking, and finally a state of torpidity from which he could scarcely arouse himself. Examination showed loss of weight, sluggishness of reflexes, slowness of movement, and difficulty of cerebation, along with a very sad feeling tone. The pulse was slow, and the blood pressure below 90. The clinical picture was typical of hypoadrenia, and the diagnosis was confirmed by recovery within a week by attention to general hygiene and the giving of adrenal substance.

CASE 8.—Pre-Adolescent Hypopituitarism.—A girl, aged eleven years, was brought by her mother, a doctor's wife, because of loss of interest in her lessons, of which she had previously been very fond; grimacing of the face in spite of all correction; equivocation and fibbing in attempts to evade her duties; and greediness amounting to gluttony. She had always been a stout child, but had become enormously so during the preceding year or two. Exploration of a possible psychological cause for this change of behavior was fruitless; so psychomotor exercises were begun for the facial ties. The only effect of these was to arouse the patient's resentment, and they were not continued. Some time after, great somnolence manifested itself, the child becoming very lethargic and even dropping off to sleep in the middle of a task or at the table for a few minutes. This directed attention to the function of the pituitary gland; so this was immediately explored by the levulose test. As this showed great increase of the tolerance of the system to large amounts of sugar, 300 grammes, it was decided that the pituitary gland was functioning insufficiently; great increase of weight, torpor, psychic inadequacy, and its attendant changes in behavior being symptoms of lack of pituitary secretion. Feeding with increasing doses of pituitary gland was at once begun.

The child recovered completely in a few months, and after the onset of puberty was able to dispense with the pituitary gland, and now 10 years later, is active and comparatively thin.

CASE 9.—Hypothyroid Torpor.—A case mentally even more sluggish was seen in a woman of 50, but in contrast to the preceding example she had gained 30 lbs. in weight in the course of a few months, the voice had become coarse and rough, there had been progressive and constant loss of hair, the eyebrows had become scanty, the urine less abundant, and she showed the characteristic thickening at the base of the neck, low temperature, slow pulse, and rough skin of hypothyroidism—a diagnosis confirmed by her rapid recovery when thyroid substance was given her by the mouth.

PSYCHOGENETIC OTTUSION.

The torpid state has been observed as a reaction to an over-difficult situation. Thus one of my friends, an eminent inventor, who keeps up a private laboratory for his amusement, finds that whenever he fails to solve a problem upon which he has been working for some hours he is not only disappointed but has an irresistible inclination to sleep, which he indulges, although it can be overcome with a powerful stimulus.

Again, a young lad of my acquaintance when faced with something which he finds unpleasant

feels himself overcome with a species of lassitude and complains of being very tired. This state is very easily dissipated by either changing the mental attitude toward his task, or by permitting him to do something else. In some instances, however, lassitude will persist for a considerable time.

THERAPEUTIC IMPORT.

Although curious and interesting, relation of these cases would have little practical import for healing of the sick did differential diagnosis not provide an avenue to treatment of each case leading to improvement and recovery. Thus, the case of acute encephalitis was spared the risks of exploratory craniotomy, avoided an unnecessary saturation with antiluetics, and he was spared the expense of a rich diet.

The patient with post-encephalitic dystonia is saved from wasting his money upon useless manipulations whether they call themselves chiropractic or not, and is spared the annoyance and expense of being bled in a vain hope of relaxing his over-tight muscles.

The patient with a tumor of the frontal lobe is relieved by an operation upon the skull; he, too, is spared the infliction of mercury and arsenicals.

The woman with pellagra escapes the madhouse, useless medication, futile exploratory operation, and is quickly restored by appropriate diet.

The young girl with pituitary disease is spared the stigma of a perverse character, the trying discipline of psychomotor reëducation, and the murdering of the digestive organs by so-called tonics. She was soon restored to effective living by proper opotherapy.

The man who at first sight seems a wreck of his former self is spared the all too commonly imposed trip to Florida, a long stay in a sanatorium, or a life of permanent invalidism. He, too, is quickly restored to effectiveness by proper opotherapy.

The woman who has become a burden to her household, and whose illness is compelling her family to face an entire readjustment of their lives, is restored to her former effectiveness as director of her household and companion of her husband and children, but only after the nature of her trouble is ascertained to be due to a mere deficiency of thyroid secretions.

Of the torpid conditions ensuing upon psychic causes, of which an example would take too long to relate completely enough, the therapeutic import of a correct diagnosis is just as great; for it is especially to these patients that have been misdirected so often medicinal and physical measures without efficacy in such cases. Strychnine, forced feeding, rest, change of scene, douches, massage, treatment by cults—all fail to reach the source of the disturbance. The inertia of cases of this kind can be quickly and infallibly removed, by proper psychic means, and by them only. For if other means, in some few cases,

seem efficacious, it is only because of the psychic accompaniments which some of them sometimes contain, and which may accidentally happen to fit the particular case; whereas intelligent psychotherapy ascertains and measures the situation and then meets it with a sure hand.

Most gratifying of all, the distress and ineffectiveness due to psychic disadaptations are permanently relieved by the rectification of the patient's mental attitude and accompanying emotion, with a success nearly invariable where proper means are used.

1746 K Street, N. W.

CONGENITAL MALFORMATION OF THE INTESTINE — ATRESIA AND IMPERFORATE ANUS.

A REPORT OF TWENTY-SEVEN CASES.

BY WILLIAM S. QUINLAND, M.D., BOSTON,

Assistant in Pathology, Peter Bent Brigham Hospital.

[From the Pathological Laboratory of the Peter Bent Brigham Hospital, Boston, Mass.]

Congenital malformation of the intestine, although not by any means a common defect, is of sufficient importance to warrant the attention not only of the practising physician, but of the laity as well.

Recently while assisting Dr. Wolbach in autopsies at the Children's Hospital, Boston, two cases of malformation of the intestine were encountered in a single week. The similarity of sex, nature of defect and operation, and the fact that both died on the fourth day, led to my studies of this particular form of defect; with the result, I was able to collect twenty-five unpublished cases from the Warren Anatomical Museum of the Harvard Medical School.

In view of the fact that text books on diseases of children, obstetrics, and systems of surgery mention the condition from their respective points of interest, it is the object of the writer not merely to place these cases on record, but to include in this study such available information, other than those that are obvious at birth, that may be of interest on the subject.

I am indebted to Dr. Stone of the Surgical Service of the Children's Hospital for the clinical data on the first four cases; and to the Warren Anatomical Museum for allowing me to use the specimens and records; also to Dr. Wolbach for the assistance he gave me in the preparation of these cases.

REPORT OF CASES.

CASE 1.—A-21-19.

Clinical Data: Baby L., male, age 2 days, was admitted to the Children's Hospital, Boston, with imperforate anus. Although no meconium was passed by urethra, the symptoms were not

urgent, as there was no distention or vomiting. The family history was negative; there being no miscarriages, syphilis or tuberculosis.

A perineal exploration was done, but the rectum could not be located. On the following day a colostomy was done, after which the patient showed marked improvement, but of short duration. His temperature varied from 97 to 102 during his stay in the hospital. He died on the fourth day, two days after the operation.

Pathological Report: Necropsy was performed 9 hrs. post mortem by Dr. S. Burt Wolbach and Dr. W. S. Quinland.

Anatomical Diagnosis: Imperforate anus, persistent cloacal duct, congenital absence of left kidney, hypertrophy of the right ventricle of heart, hypertrophy of adrenal (left), colostomy wound, perineal wound, acute peritonitis.

Body: The body was that of a newly born male baby, measuring 42 cm. in length. At a distance of 2 cm. to the right of the umbilicus was a colostomy wound 5 cm. long. This wound was closed by sutures except in its middle portion, where there was an opening 1.5 cm. long, through which feces could be expressed. In the perineal region a gaping wound 2 cm. long and 4 cm. deep was seen to enter the membranous urethra, instead of the rectum, which existed as a dilated sac high up in the pelvis.

Peritoneal Cavity: On opening the abdomen the stomach was seen to be distended with gas. The cecum and several loops of small intestine were deeply injected and matted together by fibrinous adhesions. The calibre of the gut was normal until the rectum was reached, where it became dilated to the extent of 7x5 cm., and communicated with the membranous urethra by an opening barely large enough to admit a small sized probe. The bladder was distended to its full capacity with dark brown turbid fluid, and its mucosa was deeply injected. Near the urethral orifice, two small openings were seen. One of these, situated somewhat to the right of the median line, communicated with the right ureter; the other, 1 cm. below and in the median line, proved to be a persistent cloacal duct. (Fig. 1.)

Other abnormalities present were a congenital absence of the left kidney and ureter. Hypertrophy of the left adrenal, which measured 5x4x4 cm. A right kidney shaped like a mushroom with its ureter given off from the inferior (caudal) surface. The heart was flattened so that its transverse measurement was 4.5 cm. and its vertical 2.5 cm. A Meckel's diverticulum was present.

CASE 2.—A-21-20.

Clinical Data: D. M., male, age 3 days, entered the hospital with imperforate anus. He began to vomit greenish material at birth. His abdomen became distended, but there was no tenderness. His temperature varied from 97-101. The family history was negative, father, mother, and three other children being well.

A perineal exploration and colostomy was done. The rectum was not entered, and the patient died on the fourth day, 24 hours after the operation.

Pathological Report: Necropsy was performed 1½ hrs. post mortem by Dr. S. Burt Wolbach and Dr. W. S. Quinland.

Anatomical Diagnosis: Imperforate anus, patent cloacal duct, colostomy wound, perineal wound, acute peritonitis, acute cystitis. So nearly alike were the findings in this case to the preceding one, that a less detailed description is given.

Body: The body was that of a male infant 49 cm. long. The skin was lemon yellow. There was a colostomy wound 6.5 cm. long, and 4 cm. deep that terminated behind the neck of the bladder and 1 cm. below the dilated rectum.

Peritoneal Cavity: On opening the abdomen the intestine was seen to be deeply injected and covered with a viscous exudate. The stomach was distended. The lumen of the gut was normal, until the rectum was reached, where a dilatation of 6.5x3.5 cm. was encountered. This sac-like dilatation communicated with the prostatic urethra by a patent cloacal duct 2 mm. in diameter. (Fig. 2.) The mucosa of the bladder was markedly congested and oedematous. Other abnormalities were a bifid left thumb and much dense fibrous adhesions around the common bile duct.

CASE 3.—A-18-2.

Clinical Data: L. H., male, age 6 days, entered the hospital with persistent vomiting of dark foul material that started on the second day. The abdomen was markedly distended and tympanitic. The superficial veins of the abdomen were engorged, and active peristalsis could be seen through the abdominal wall. The external anus, which was patent, had many fissures around it. The family history was negative; father, mother and one other child were alive and well. An ileostomy was done, but the patient died very shortly after the operation.

Pathological Report: Necropsy was performed by Dr. S. Burt Wolbach.

Body: The body was that of a poorly nourished male infant measuring 54 cm. in length. At a distance of 2 cm. to the left of the umbilicus was a surgical wound 8 cm. long, with sutures intact.

Peritoneal Cavity: On opening the abdominal cavity, there was seen to be a complete break in the continuity of the gut so as to form a proximal and distal cul-de-sac in the middle third of the ileum. The proximal blind end was dilated to 3 cm. and had a surgical opening that was sutured to the abdominal wall. Connecting this proximal end to a collapsed similarly blind distal portion were two narrow glistening white cords of fibrous tissue, each about 1 mm. thick and 3 cm. in length, and a portion of mesentery above. The distal part of the ileum was tightly contracted, but on incision was found to be

patent and empty. It led to a completely contracted cecum in approximately normal position. There was a normal appearing appendix coming from the posterior wall of the cecum. The ascending, transverse, descending colon, and sigmoid flexure and rectum were tightly contracted and empty, so as to resemble more nearly small intestine than large. This description of the defect is best illustrated in Fig. 3.

CASE 4.—A-16-4.

Clinical Data: S. B., female, age 3 days, was admitted to the hospital with abdominal distention and persistent vomiting of everything ingested since birth. No meconium was passed, although a patent anus which would not admit the tip of the fifth finger was present. Family history was negative. Father, mother and five children alive and well.

An enterostomy and perineal exploration was done. The rectum was, however, not entered and the patient died five hours after the operation. Here again, because of the close similarity of the defect in this case to that of the preceding, I shall only mention some of the more important findings.

Pathological Report: Necropsy was performed by Dr. Wolbach.

Body: The body was that of a female infant 43 cm. long, weighing 2400 grams. Above and below the anal orifice were surgical incisions 1 cm. long, and closed by sutures. An enterostomy wound 4 cm. long and 4 cm. to the left of the umbilicus was present.

Peritoneal Cavity: On opening the abdomen a defect quite similar to the preceding case was encountered in the upper third of the ileum. Following is a summary including the foregoing cases with twenty-three others collected from the Warren Anatomical Museum.

DISCUSSION.

Although there are various developmental defects of the intestine and its related structures, namely, atresia, stenosis, imperforate anus, diverticula and cyst, I shall attempt only to discuss those conditions encountered in the cases of the present issue. For convenience I shall begin with imperforate anus; not merely because of the clearer and more general conception of its occurrence, but it is the condition most frequently met, and that which is less likely to escape the immediate detection of the accoucheur.

Imperforate Anus: The embryology in this instance is interesting. Quoting Gaston⁶: "About the first month, the invagination of the ectoderm of the skin takes place on the ventral side of the embryo, opposite to the terminal portion of the cloaca, by which the ectoderm is brought into contact with the entoderm of the lower end of the intestine, the two layers becoming the cloacal membrane. When the cloaca becomes sub-divided into the urogenital sinus

and the rectum, the cloacal membrane is correspondingly separated into the urogenital aperture and into the anal membrane. About the end of the twelfth week the anal membrane ruptures forming the anus." Imperforate anus, then, results from imperfect union between the rectum above and the posterior part of the cloaca common to the urogenital aperture and the hind gut below. The deformity exists in varying degrees. The anal aperture may be separated from the rectum by mesodermal tissue an inch or more in depth as a result of insufficient invagination of the ectoderm to meet the rectum, which may end blindly above or communicate with the exterior by some unusual opening. Cases 6, 12, 15, 16, 19, 20 and 22 fall in this category. Another type is where the embryonal anal plate persists without the slightest invagination of the skin in this region. See Cases 1, 5, 10, 11, 13, 21, 23, 24, 25, 26, 29.

In the presence or absence of an external anus, if for some reason complete separation of the cloaca to form the urogenital sinus and rectum does not occur, the latter opens into the bladder, or more commonly into the prostatic or membranous urethra if the child be a male. See Cases 1, 2, 10, 13, 14, 26 and 27; or the rectum may open into the vagina if the child be a female. See Cases 11 and 25. From these types of imperforate anus, it can readily be seen how seven of these cases might have gone unrecognized at birth because of the presence of an external anus that did not communicate with the intestine above. Still more unusual openings of the rectum have been recorded in the literature; among them being two extraordinary cases cited by Bushe where in the case of Dinmore's an infant in whom the inferior portion of the abdomen was badly developed had the intestine directed upward, and opened under the border of the right scapula; and to that of Bils, in which the intestine mounted from the pelvis, through the chest, into the neck, and opened on the face by a very small opening.

ATRESIA.

Although many hypotheses relative to the causation of atresia of the intestine have been propounded, among them being bands of adhesions, twists and bends of the gut, blocking of mesenteric vessels resulting in defective blood supply, etc., none of these seem to give a very satisfactory explanation for the complete break in the continuity of the gut in the small intestine. Primarily, the duodenum presents a well defined round lumen in embryos of about 7 mm. This lumen later becomes divided into compartments by septa of proliferating lining epithelium so that in embryos of about 14 mm. the lumen may be completely occluded. At 30 mm. the compartments begin to become confluent, and in this way a central lumen is re-established. The view most commonly held is that of Tandler¹⁰ based upon the above briefly outlined embryology. Forsner¹¹ confirmed Tandler's views to the

FIG. 1. Case 1. Ch. Hosp. A-21-19.—Imperforate anus, congenital absence of left kidney. Persistence of cloacal duct which enters bladder; on posterior wall median line, level of right ureteral orifice.

FIG. 3. Case 3. Ch. Hosp. A-18-2.—Congenital atresia in middle third of ileum, showing dilated proximal cul-de-sac and the contracted distal cul-de-sac attached to each other. The deformity falls in Group III (b) of Forsner's classification.

FIG. 2. Case 1. Ch. Hosp. A-21-19.—Imperforate anus. Persistence of cloacal duct, both entero-prostatic urethra.

FIG. 4. Case 3. Ch. Hosp. A-18-2. Microscopic drawing of a longitudinal section taken through the distal cul-de-sac, showing no variation of the coats around the blind end.

ANOMALIES								
No.	Date	By whom presented	Sex	Character of Lesion	Anatomical Situation	Treatment and Result	Remarks	
1	1901	Dr. S. B. Wolbach Dr. W. B. Guilford	Male	Imperforate anus.	No external anus. Rectum ends as cul-de-sac 7.5 cm. below anal opening that communicates with the prostatic urethra. Small amount of fecal matter in rectum. Three lobes to left.	Operation - Perineal exploration. Following day a colostomy was done. Died on the fourth day, two days after the operation.	Meckel's diverticulum was present. Patient showed marked improvement of short duration immediately after the colostomy. Autopsy showed acute peritonitis.	
2	1901	Dr. S. B. Wolbach Dr. W. B. Guilford	Male	Imperforate anus.	No external anus. Rectum ends in cul-de-sac 6.5 x 3.5 cm. having small opening in prostatic urethra.	Operation - perineal exploration and colostomy. Died on the 4th day, 24 hours after the operation.	Patient drained freely during the night following operation, but rapidly grew weaker. Stimulants were used without success. Autopsy showed acute peritonitis. Rectum not visible at perineal orifice. Slight right thumb.	
3	1910	Dr. S. B. Wolbach	Male	Atresia	Blind ends in cul-de-sac in middle third. Remainder of intestine is tightly contracted.	Operation - Ileostomy. Died on 4th day shortly after the operation.	There were several small fissures about the anus.	
4	1916	Dr. S. B. Wolbach	Female	Atresia	Blind ends in cul-de-sac just below jejunum where it is 8 times the width of the large intestine which measures 7 cm. across. Anus is patent.	Operation - Enterostomy. Perineal exploration. Died 5 hours after operation.	Anus although patent, will not admit the tip of the little finger. Feces can be inserted through anus for only 1/4 in. The rectum was not entered at operation.	
5				Imperforate anus.	Rectum ends blindly above anus. No external anus.		Museum specimen - No record.	
6		Dr. R. H. Stone	Male	Atresia	Rectum ends in cul-de-sac 3 cm. above the anus which is of normal size.	Operation. Trochar was passed on the eighteenth day. Died on the 24th day.	Rectum and anus were separated by a small amount of tissue. No opening between bladder and urethra.	
7	1895			Atresia	Duodenum ends in cul-de-sac 5 cm. wide. Bands of mesentery connect duodenum with intestine below which measures only 5 cm. wide. Constriction below pylorus. Esophagus dilated.	Died on sixth day.		
8	1892	Dr. Garrett		Atresia	Duodenum ends in cul-de-sac and is enormously dilated 4.5 cm. Head of intestine well formed and collapsed. Blind end of jejunum .7 cm. wide.	Died on third day.	Child at term.	
9	1889	Dr. R. H. Stone		Atresia	Duodenum ends in cul-de-sac and dilated 4 cm. Sile duct splits just below into otherwise well formed intestine.	Died on seventh day.		
10	1877	Dr. R. H. Stone	Male	Imperforate anus.	No external anus. Rectum opens into bladder. Urethra dilated and courses along the outside of bladder to the penile urethra. Penis rudimentary. Urethra divided.	Died.	There was a structure corresponding with the seat of the verrucosities.	
11	1877		Female	Imperforate anus.	No external anus. Rectum ends blindly with small opening into vagina.	Operation - Died.		
12	1877		Male	Atresia	Rectum ends blindly above the anal orifice from which it is separated by fibrous tissue.	Operation - Died.		
13	1877		Male	Imperforate anus.	No external anus. Atresia of rectum with opening in prostatic urethra.	Operation. Perineal exploration. Died.		
14	1877		Male	Imperforate anus.	No external anus. Rectum dilated and enters the membranous portion of urethra.	Operation. Perineal exploration. Died.		
15	1869			Imperforate anus.	Rectum ends in cul-de-sac a few cm. above anus.	Operation. On the 4th day a trochar was passed. Opening was enlarged. Died on the 6th day.	Meconium passed freely after the use of trochar, which passed through the surrounding tissue into peritoneal cavity.	
16	1858	Dr. James Carr	Female	Atresia	Rectum ends in cul-de-sac separated by narrow bands of tissue from anus which is formed.	No operation. Died on sixth day.	Second child in the family with atresia of the intestine. The previous one, a male, lived 8 days, during that time he passed meconium per urethra.	
17	1856	Dr. Stevens		Atresia	Anus. At birth a small probe only could be passed. But it became somewhat dilated later. Intestine was dilated above.	No operation. Died at 18 months.		
18				Atresia	Duodenum, ends as dilated cul-de-sac 4.5 cm. wide. Not connected with ribbon like intestine of .5 cm. width.	No operation. Died on 5th day.		
19	1840	Dr. W. Porter	Male	Atresia	Patent external anus that admitted the finger to a depth of half an inch. Rectum about 3 cm. above.	Operation. Anus was further opened by incision 1/2 inches upward. Died few hours later.	The intestine was not entered at operation.	
20	1837	Dr. A. B. Leach	Female	Imperforate anus.	Atresia of Rectum, two above anus. Separated from 1 inch of rectum immediately above anus by less than an inch.	Operation. Trochar was passed through the anal plate for about 2 inches on the third day. Died two days later.	The trochar failed to enter the intestine.	
21	1837	Dr. J. C. Warren		Imperforate anus.	Atresia of ascending colon. Cecum measures 5 x 3 cm. Attached distally is a blind atrophic and 3 x .8 cm. representing the remainder of the large intestine.	Died in a few days.		
22	1840	Dr. John Flint	Male	Atresia	Patent external anus with one half inch of intestine above. Upper intestine ran a straight course and terminated in cul-de-sac about 4 cm. above anus.	No operation. Died on the eighth day.	Operation was not done possibly because there was a patent external anus.	
23	1839		Female	Imperforate anus.	No external anus. Atresia of rectum above the anus.	Perineal exploration. Died 17 hours after.	The posterior perineal fold of the vagina was extensively excised, resulting in profuse hemorrhage. Intestine not entered.	
24	1840		Male	Imperforate anus.	No external anus. Rectum ends in cul-de-sac a short distance above the anus.	No operation. Died on the fourteenth day.	The lower portion of the small intestine and the whole of the large were inflamed. Large intestine was ulcerated.	
25	1839	Dr. Walker	Female	Imperforate anus.	External anus absent. Rectum ends in cul-de-sac about 4 cm. above anus, and communicates with upper posterior vagina by small opening.	Colostomy. Died at 3 months.	Two or three weeks before death the colostomy wound healed and feces was passed as before by the vagina.	
26	1837	Dr. J. H. Lane	Male	Imperforate anus.	No external anus. Rectum dilated and ends in cul-de-sac with auxiliary opening into the membranous urethra.	No operation. The patient was kept under the influence of paregoric. Died on the ninth day.	Developed broncho-pneumonia as a terminal infection.	
27	1910	Dr. W. D. Chamberlain	Male	Imperforate anus.	No external anus. Rectum ends in cul-de-sac with anus opening into the membranous urethra. Penis rudimentary. No scrotum.	Died.	No available record of treatment.	

effect that a condition of more or less complete occlusion of the duodenum may persist in the human from the very early embryological stage (5 mm. to 30 mm. in embryos), in which it normally occurs, until birth. The persistence of the epithelial septa is followed by an ingrowth of mesenchyma. Forssner found such atresias in the human colon and esophagus. He confirmed Tandler's work. Kreuter⁸ also finds it in the colon. Forssner⁴ quotes numbers of authorities giving such epithelial occlusions of the intestinal tract in various animals,—fowls, frogs, guinea-pigs, rabbits, dogs, and swine. He confirms these findings in the normal embryo of man's duodenum, rats' and fowls' duodenum, as the above sequence in the development of the intestine. He gives the following classification of the defect.

Group I. Septa of mucous membrane (a) with epithelium wholly intact. (b) Loss of epithelium in places (irisform).

Group II. Blind ends connected with a strand composed of serosa, muscularis and submucosa. In the submucosa one finds (a) No epithelium. (b) Only an occasional epithelial rest. (c) A small epithelial tube joining the blind ends.

Group III. Free blind ends (a) Not attached to each other. (b) Attached to each other.

The etiological factor of intestinal atresia and stenosis is to be found in the embryonal occlusions. One can interpret the subsequent pathogenic development as follows. If the epithelial occlusion does not disappear when the fold-building process through the ingrowth of the mesenchyma begins, then the ingrowth of the mesenchyma into the epithelium occurs before the continuity of the tube is re-established. (A partition.) If the connective tissue bridge is thin, then it provides a membrane. If it is thicker, it becomes a cord. If the connective tissue bridge is not complete or is very delicate at one place so that it tears, an incomplete membrane is formed. Through modification occurring during fetal life the various forms of atresia and stenosis can occur. It is possible to have a malformation which originally was a stenosis develop into atresia, which accounts for the fact that meconium is sometimes found distal to the atresia, if such a defect is formed after the third month. Atresia of the esophagus is to be explained in the same manner, but in addition the very early communication between the esophagus and trachea must be taken into account. It is further stated, that the gut fails to expand owing to the large size and downward growth of the liver at this stage, and to pressure exerted by the mesodermal wall on the closed epithelial cord.

In order to determine as nearly as possible

in my cases what histological changes had occurred in places where the gut was occluded, I made longitudinal and cross sections through the terminal portions of the proximal and distal cul-de-sacs of Kaiserling fixed preparations. The sections were stained with hematoxylin and eosin. Microscopically none of the sections showed any evidence of scarring in the coats, no intervention of fibrous tissue or proliferation of epithelium between the walls of the gut or anything that would suggest a healed inflammatory process. On the contrary, the mucosa, submucosa, muscle and serous coats were seen in longitudinal sections to course without any apparent variation in thickness from one wall of the intestine around the blind end, to the opposite wall. These observations, which are quite consistent with those of Forssner,⁵ were best studied in sections taken from the distal cul-de-sacs where there was absence of dilatation. (See Fig. 4.) Sections taken from the proximal cul-de-sacs showed the above changes with less distinctness, due on the one hand to stretching of the coats, and on the other to a localized acute inflammation either as a result of accumulated meconium, or an enterostomy operation. In some of the cases the walls of this portion of the gut were definitely thickened and discolored dark red. Microscopically, sections from the thickened wall showed hypertrophy of the muscle coat and irregular losses of mucosa. Sections of bands of fibrous tissue (apparently mesentery) that joined the proximal and distal cul-de-sacs were also examined microscopically to determine if possible to what extent thrombosis plays in the formation of such defects; but no blood vessels could be found in any of the sections. From these observations and the works of other investigators, I am inclined to believe that the break in the continuity of the gut is due to embryonic arrest in development, rather than to some mechanical injury of which it may be the end-result.

OCCURRENCE.

Location: Atresia of the intestine may occur in any portion of the intestinal tract. In twenty of the cases herein presented it occurred in the rectum; once in the ascending colon, twice in the ileum (first and middle thirds), and four times in the duodenum. From so few cases as these, it is wholly impossible to arrive at any definite conclusion as to what portion of the intestine the defect is most likely to occur; yet, statistics record the majority of cases to occur in the duodenum and the jejuno-ileum regions. Just how many of these cases occur each year it is difficult to say with any degree of certainty, since it may be assumed that a few are likely to go unrecognized; but judging from the figures given below it may be concluded that the condition is one of the rare forms of congenital malformations. I am indebted to Drs. F. S. Newell, Boston Lying-In Hospital; J. B. DeLee, Chicago Lying-In Hos-

pital and Ross McPherson, New York Lying-In Hospital, for the following data. In the last 10,000 confinements at the Boston Lying-In Hospital, only one case of imperforate anus was encountered.

In 10,000 cases at the Chicago Lying-In Hospital two cases were encountered. In 50,000 cases at the New York Lying-In Hospital, there were 28 cases of atresia and imperforate anus; 24 of these were males and 4 were females.

PROGNOSIS.

The prognosis is usually grave on account of complications; hemorrhage, peritonitis and septicæmia. According to Bevan,² because of the probability of an ascending nephritis developing, it is usually wise in these cases of imperforate anus where there is connection between the lower end of the rectum and the bladder, to be satisfied with a permanent colostomy opening, and not risk the life of the patient in an attempt to separate the rectum and the bladder. If, however, the child be a female, the prognosis is more favorable, particularly if the recto-vaginal opening is of fairly large size. Gay cites a case of Morgagni in which Tatonicus, a Jewess, passed all her feces by the vagina and lived to the age of 100 years. Of Dr. Ross McPherson's 28 cases, 17 died, 10 lived, and one was a stillbirth. Death occurs usually in 5 or 6 days if the occlusion is high up in the small intestine. Atresia and imperforate anus are sometimes complicated by other anomalies that may or may not influence the prognosis of the case. This depends largely on the location and extent of such a defect. See Nos. 5, 2, 10 and 27.

TREATMENT.

Surgical invention is the only treatment. Because of the variation in defect, the procedure must necessarily be modified to best meet the requirements of the existing condition. The perineal approach, which is the one frequently adopted, is sometimes futile on account of the very limited incision through which the surgeon is compelled to explore the deeper perineal structures, in an attempt to find the rectum, which might terminate high up in the pelvis. In such an event, an enterostomy is resorted to.

The antiquity of the operation as given by Thom³ dates from eighteen hundred years ago; the first recorded instance being that of Egineta. Bell of England, in 1787, was the first to adopt the rational procedure of dissecting through the perineum and searching for the rectal ampulla. The first successful operation by this method in the United States was performed by Campbell, 1790. While to Amusat of Paris in 1835, and somewhat later to Verneuil, belongs the honor of perfecting the operation as it is now performed; i.e., dissecting through the perineum without injury to the sphincter muscles, searching for the rectum, opening it, and suturing the bowel to the perineal incision.

SUMMARY.

Atresia and imperforate anus may be regarded as rare forms of congenital malformation of the intestine due to embryonic arrest in development. The defect occurs once in about 15,000 infants, and may be found in any portion of the intestine from the duodenum to the rectum.

It is uncertain whether the malformation is in any way influenced by hereditary tendencies, since it is impossible to arrive at definite conclusions from so few cases as these. Only one of this collection, No. 16, gave a history of another child in the family having passed feces per urethra. The prognosis is grave on account of complications, particularly in males, in which sex the malformation is more frequently present. Of these 27 cases 13 were males, 6 were females, and in the remaining 8 the sex was not given. The only treatment is surgical.

Ordinarily, the presence of a patent external anus furnishes enough proof that the intestine is well formed; but from the foregoing observations it is obvious that one cannot emphasize too strongly the importance that should be attached to the first bowel movement in the new-born, since a break in the continuity of the gut is sometimes present.

It is of further interest to note that in the following cases no operation was performed.

- No. 16—Atresia, died on the 6th day.
- No. 18—Atresia, died on the 5th day.
- No. 22—Atresia, died on the 6th day.
- No. 24—Imperforate Anus, died on the 14th day.
- No. 26—Imperforate Anus, died on the 9th day.

The fact that these five cases lived over a period of from five to fourteen days without operation, makes it more apparent that early operation in every instance should be resorted to as a means to a more favorable prognosis.

TREATMENT OF DIABETIC GANGRENE.

BY HOWARD F. ROOT, M.D., BOSTON.

[From the Diabetic Clinic, New England Deaconess Hospital.]

GANGRENE occurring in the elderly diabetic patient has long been regarded with discouragement by both surgeon and physician. The tedious, if not eventually unsatisfactory, course

of conservative treatment, and the frequency of coma following amputation have rendered it one of the most serious of the complications of diabetes. The following seven consecutive cases illustrate successful surgical treatment, the importance of the diet in preventing postoperative acidosis, and suggest possible prophylactic measures.

CASE HISTORIES.

CASE 1. Joslin 1332, Hebrew, roofer, aged 61 years, admitted September 21, 1920. Onset of diabetes in 1906. Three months previously he noticed pain, redness and swelling of the left great toe. During the last three weeks ulceration with purulent discharge had been accompanied by increasing pain. Inflammation and oedema involved the entire toe, tarsal-metatarsal joint, and dorsum of the foot. On the plantar aspect an ulcer with a deep sinus apparently communicated with the joint. Pulsation was felt in the dorsalis pedis, posterior tibial and popliteal arteries, but the radial and brachial arteries and retinal vessels gave evidence of advanced arteriosclerosis. The urine contained a slight trace of albumin, sugar 1.9 per cent., acetone $++$, and no diacetic acid. X-ray showed marked calcification of the dorsalis pedis and posterior tibial arteries.

Owing to the patient's objections immediate operation was not urged. Active motion, massage and heat were applied locally and the patient kept in bed. After three days the left great toe became black, with a sharp line of demarcation somewhat above the tarsal-metatarsal joint.

On September 28, under spinal anesthesia, Dr. R. C. Cochrane amputated the left leg at the junction of the upper and middle thirds. Recovery was uneventful and the patient was discharged on the forty-third day.

CASE 2. Joslin 1993, English auditor, aged 62 years. First seen November 19, 1920. Diabetes was discovered in an insurance examination in 1917. He had followed no special diet, as he "thought it might work out all right." One month before, his fourth toe on the left was pinched by a tight shoe. One week later, his physician found an infected corn with gangrenous borders extending anteriorly to the nail. Two weeks later, two terminal phalanges were removed under cocaine. The next joint was then involved, and within a few days the third toe became discolored. When he was admitted to the hospital on November 23, a deep, sloughing ulcer with gangrenous edges extended backward between the third and fourth toes, with oedema and redness as far as the ankle joint. Pulsation in the dorsalis pedis was barely palpable. Temperature was 100 degrees. Urine—Albumin, slight trace; sp. gr., 1026; sugar, 2.1 per cent.; diacetic acid, $++$. Numerous hyaline and granular casts. Blood sugar 0.35 per

cent., before breakfast. All blood sugar estimations recorded in this paper were made on fasting specimens.

On November 24, under spinal anesthesia, Dr. R. C. Cochrane amputated the leg at the juncture of the upper and middle thirds. Following operation the temperature fell to normal and remained so. No diacetic acid was present at any time after the operation. Recovery was uneventful and the patient was discharged on the thirty-seventh day.

CASE 3. Joslin 2173, an American housewife, aged 66 years. Admitted April 17, 1921. Diabetes was discovered in 1918 when she had a cerebral hemorrhage. Three months previously she burned her foot on a hot soap stone in bed, and poulticed it with linseed meal. Thirteen days before she had experienced increasing pain. During the preceding three days, at another hospital, her temperature had remained about 100 degrees, and she had received three grains of codein for her pain. On the plantar surface of the left foot was a large, deep ulcer with gangrenous borders. Oedema, redness and heat extended over the entire plantar surface and onto the dorsum as far as the ankle. Advanced arteriosclerosis of the peripheral vessels, with marked retinitis and optic neuritis, was present. Urine—Sp. gr., 1026; albumin, large trace; sugar, 0.9 per cent.; diacetic acid, 0; sediment, many pus cells. Blood sugar, 0.36 per cent.

On the day of admission, under gas anesthesia, a preliminary incision showed that the entire subcutaneous tissue on the plantar surface was necrotic; the plantar fascia was gray and sloughing at several points. On April 18, under spinal anesthesia, Dr. R. C. Cochrane amputated the leg at the juncture of the upper and middle thirds. The wound healed by first intention, and she was discharged on the thirty-third day. On January 15, 1922, she returned with a pressure sore on the knee. Blood sugar was 0.09 per cent., and her urine was sugar free. She was discharged after three days' stay.

CASE 4. Joslin 2339, Hebrew merchant, aged 70 years; duration of diabetes, eight years. First admitted on September 8, 1921, because of severe pain in his left foot. At that time the left great toe was cold and blue, and on its medial surface was a purulent bleb. Pulsation was felt in the posterior tibial, but not in the dorsalis pedis artery. Urine contained 2.5 per cent. sugar, albumin a slight trace, and a moderate number of leucocytes. Blood sugar was 0.25 per cent. Blood urea nitrogen was 27.6 mgm. per 100 c.c. The bleb was opened. While in bed, with massage and active hyperaemia, the toe became warm and normal in color, and the pains improved. The urine showed only a trace of sugar at discharge two and a half weeks later.

He reentered October 26, complaining of severe pains in the leg. On the dorsal surfaces of the great toe and the third toe were ulcerated areas with gangrenous borders. The foot was cold and discolored. Urine contained 0.4 per cent. sugar and his blood sugar was 0.23 per cent. On the day following, under spinal anesthesia, Dr. D. F. Jones amputated the leg at the mid-thigh. Recovery was uneventful, and he was discharged on the thirty-third day.

CASE 5. Joslin 2311, an English salesman, aged 58 years, admitted August 15, 1921. Onset of diabetes August, 1913. Since that time sugar and albumin had been present in his urine whenever examined. Six weeks previously the third toe of his left foot became discolored and cold. Ten days ago the skin broke between the second and third toes. A deep ulcer with gangrenous borders extended back along the tendons. The peripheral vessels showed marked arteriosclerosis. Blood pressure was 220/120. Urine—Sp. gr., 1.007; albumin, large trace; sugar, 0.2 per cent.; diacetic acid, 0; sediment, 15 to 20 hyaline and granular casts per high-power field. Numerous W. B. C. Blood sugar, 0.26 per cent. Non-protein nitrogen, 45; phenolphthalein, 19 per cent.

During the first week he remained in bed and the foot was dressed daily with sterile salt dressings. The urine became sugar free and the blood sugar fell to 0.13 per cent. He continued to have severe pain in the foot and leg, which interfered with his sleep. At the end of this time the ulcer had in no way improved and the second toe had become cold and cyanotic. X-ray showed marked calcification of the dorsalis pedis and posterior tibial arteries. As it was evident that, in spite of the improvement in his general condition, the condition of his foot was decidedly worse, operation was advised. An attempt at spinal anesthesia failed because of marked hypertrophic arthritis of the spine. No muscular relaxation could be secured under gas and oxygen, and finally etherization was resorted to with many misgivings. Dr. E. C. Cochrane amputated the leg at the mid-thigh. Following operation acetone appeared in the urine during the first few days only. Blood pressure was 170/90 the day following operation, 160/110 on the seventh day, and 145/85 at discharge five weeks later.

CASE 6. Joslin 2237, an American lawyer, aged 62 years. Diabetes was discovered in June, 1920. On April 1, 1921, he pricked a blister resulting from a slight burn on his right foot. The foot became infected and a cellulitis developed which extended above the ankle. The foot was thrice incised in June and July, but did not heal. X-ray showed osteomyelitis of the head of the fifth metatarsal and the proximal end of the first phalanx, and calcification of the dorsalis pedis artery. On August 25, Dr. R. C. Cochrane amputated the leg at the juncture of

the upper and middle thirds, under spinal anesthesia. Recovery was uneventful and he was discharged on the seventeenth day. On December 1, 1921, his blood sugar was 0.11 per cent. and the urine was sugar free.

CASE 7. Joslin 2382, a Hebrew, male, aged 64 years. Diabetes was discovered in 1913. He was admitted October 14, 1921. During the preceding two weeks his right foot had been cold and painful. The peripheral vessels were markedly sclerosed, and no pulsation could be felt in the dorsalis pedis or posterior tibial arteries on the right. The right great toe was cold, blue and tender. X-ray—Marked calcification of the dorsalis pedis and posterior tibial arteries. Urine—Sugar, 6.5 per cent; diacetic acid, 0.

He remained in bed for seventeen days, the foot being kept warm and dry. Massage of the leg and active exercises at the ankle-joint were carried out. The blood sugar fell to 0.12 per cent., 0.13 per cent., and 0.14 per cent. on three different occasions, while the urine contained 0.1 per cent. or 0.2 per cent. sugar. At the end of this time, on the great toe and the second toe, two definitely gangrenous areas had appeared, and the entire foot, up to a point midway between the tarsal-metatarsal junction and the ankle, was cyanotic and cold. Under spinal anesthesia, Dr. D. F. Jones amputated the leg at the mid-thigh. At operation the femoral artery was found to be plugged almost to the mid-thigh with an organizing clot. At no time after operation did the patient show any acidosis. He became sugar free after ten days and was discharged in four weeks.

Etiology.—In these seven cases the average age was 63 years, and the average duration of diabetes, before the onset of gangrene, was six years and five months. Three of the seven patients were Hebrews, two were English and two American. All had been overweight prior to the onset of diabetes, and with one exception their occupations in earlier years had required little muscular activity. These facts may bear some relation to the extreme degree of arteriosclerosis, which was the most important immediate etiological factor. The diabetes was originally mild, or, at most, moderate in degree, as evidenced by its long duration and fairly ready susceptibility to treatment. Yet in the first three cases the fasting blood sugar was 0.30 per cent. or more, indicating the danger of neglecting treatment even in mild diabetes. Trauma had occurred in four cases, and in every instance neglect or unwillingness to accept advice delayed either prompt or radical treatment. In only three instances did the gangrenous process begin without any known or obvious trauma. The importance of painstaking surgical care for minor traumatic lesions of the feet, such as blisters, abrasions, corns, ingrown nails

and slight burns, cannot be overemphasized in relation to the prevention of gangrene.

Anesthesia.—The choice of anesthetic was considered of prime importance. Six patients had spinal anesthesia with novocaine. In no instance was any deleterious effect noted, and in contrast with ether practically no acidosis occurred after operation. In one patient marked hypertrophic arthritis of the spine made spinal anesthesia impossible. This patient, No. 5, a powerful man, did not relax under gas and oxygen, and therefore was given ether, in spite of hypertension and chronic nephritis.

Diet.—Once the patients were in the hospital

decision as to operation rested with the surgeon. In two cases operation was performed within twenty-four hours of admission. During this time fat was omitted from the diet and carbohydrate in the form of orange juice and oatmeal gruel was given. In the other cases, where the preoperative period varied from one to three weeks, moderately restricted diets, with a preponderance of carbohydrate, were employed. No patient was fasted.

The following table summarizes the diets given previous to operation, during the three weeks following operation, and the diet at discharge:

TABLE 1
AVERAGE DAILY DIETS

Case	Preoperative Time				Postoperative											
	In	C	P	F	1st Week			2nd Week			3rd Week			At Discharge		
					C	P	F	C	P	F	C	P	F	C	P	F
Hospital																
I—7 Days	—	78	52	10	58	44	24	50	58	35	59	62	47	75	71	54
II—1 Meal	—	20	23	0	77	43	20	58	40	33	63	51	44	96	67	54
III Immediate operation					114	51	10	60	42	34	68	47	35	114	59	65
IV—1 Day	—	32	34	45	38	23	34	33	35	48	30	33	57	45	41	70
V—8 Days	—	41	25	24	75	33	33	58	43	69	69	51	82	86	64	86
VI No food before operation					71	45	43	70	65	80				60	68	72
VII—17 Days	—	51	42	46	32	44	33	35	44	50	41	50	73	65	55	75

NOTE: C=carbohydrate, P=protein, F=fat.

Only one patient entered the hospital sugar free, and he had been under observation for some time at his home. No operation was postponed in order to get the patient sugar free, and indeed five operations were performed in the presence of both glycosuria and hyperglycemia. Yet every patient left the hospital sugar free. The following table gives the blood sugar values during the preoperative period, three weeks postoperative, and at discharge:

TABLE I:
BLOOD SUGAR PERCENTAGES
(Before Breakfast)

Preoperative	Postoperative			
	1st Week	2nd Week	3rd Week	At Discharge
I—0.30—0.29	0.37—0.30	0.25	0.24	0.15
II—0.35	0.32	0.22	0.19	0.16
III—0.36	0.36		0.20	0.15
IV—0.23		0.20	0.17	0.11
V—0.26—0.13	0.24	0.16	0.13	0.13
VI	0.17	0.19	0.10	0.10
VII 0.12—0.14	0.15	0.13	0.11	0.14

NOTE: Analyses were made by the Folin-Wu method.

Discussion.—That the course of gangrene with infection occurring in diabetics differs from that of non-diabetic patients has long been recognized. Lambert and Foster have reported cases illustrating the extraordinary improvement in the local condition with dietetic treatment which removed acidosis and glycosuria. They state that many cases of so-called "diabetic gangrene" are really no more than acute

infections whose course is modified by the presence of diabetes. In such cases they found that diabetic treatment, together with drainage of pus pockets, removal of sloughs, and formalin dressings, resulted in normal granulation and ultimate recovery without amputation. Stettin, himself a surgeon, also advocates conservative treatment.

However, in another group, best illustrated by five of these patients, the process must be regarded, at least from the therapeutic standpoint, as arteriosclerosis plus infection complicated by diabetes. When extreme arteriosclerosis, with partial or complete occlusion of the arteries supplying the part, exists, the local process must advance in spite of improvement in the diabetes. In four of the cases cited conservative treatment, *i.e.*, rest in bed, diet to reduce hyperglycemia and glycosuria, elevation of the foot, massage, active and passive hyperaemia—was tried for periods varying from one week to four months. In each instance, in spite of the patient's becoming sugar free and having normal blood sugar, pain continued and the gangrenous process advanced. Granting that diabetes may have an etiologic relationship to the arteriosclerosis in the first place, diabetic treatment will not repair the arterial damage at such a late stage. Roentgenograms are most valuable in giving evidence of calcification of the arteries, osteomyelitis or joint destruction. Calcification of arteries strongly suggests the uselessness of delaying amputation, especially if bone and tendon destruction have also occurred. With such patients delay is dangerous.

In the presence of advanced peripheral arteriosclerosis, lowered renal and circulatory function may be expected. Of the patients here reported three excreted from 12 to 40 per cent. phenolphthalein in two hours ten minutes; four had hypertension ranging from 160 to 220 mm. mercury; three had definitely enlarged hearts; seven had albuminuria; four had albumin plus casts in the urine; and four had non-protein nitrogen values in excess of 40 milligrams per 100 c.c. of urine. Not only acidosis but circulatory failure or renal complications were to be considered.

Spinal anesthesia in no instance was accompanied by evidence of shock or increase of acidosis. The patients were given from 2000 to 3000 c.c. of fluid daily, including cocoa shells, broth, weak tea and coffee. The salt in the diet was limited to five grams daily, and often was less, as indicated by the salt in the urine, which varied from two to six grams daily during three weeks after operation. The protein in the diets varied from seven-tenths of a gram to one gram per kilogram body weight. Most important in the prevention of acidosis was an excess of carbohydrate over fat, and the avoidance of such radical changes in the diet as fasting in the effort to render the urine sugar free. Elderly patients do not bear fasting well under favorable circumstances and at the time of operation fasting is fraught with grave danger.

SUMMARY.

1. Seven cases of diabetic gangrene with successful operative treatment are reported.

2. The prevention of gangrene of the feet in diabetes depends upon

(a) Conservation of the circulation by special exercises, massage, and rest.

(b) Avoidance of such practices as cutting corns, pricking blisters, cutting toe nails too closely.

(c) Careful aseptic surgical treatment of minor lesions, such as blisters, corns, burns, etc.

3. The first step in the treatment of infections is to secure circulatory support by elevation of the foot.

4. If gangrene and infection are established, amputation is indicated so soon as non-operative surgical treatment ceases to give definite improvement.

5. Decision as to operation should always rest with the surgeon. Operation is possible and practicable even in the presence of sugar, acidosis or both.

6. Patients, especially if fat or aged, should not have fasting treatment in preparation for operation.

7. During 48 hours before and after operation the diet should consist of a moderate supply, or for a diabetic a liberal supply of carbohydrate food amounting to 50 or 100 grams daily in the form of such easily digested articles as orange juice, oatmeal gruel with

skimmed milk, shredded wheat, Uneceda biscuit and egg albumin.

8. Spinal anesthesia is the first choice, gas and oxygen the second, and ether should be used only as a last resort, and then for the briefest space of time.

HYDATID CYST OF THE LUNG.

REPORT OF TWO CASES.

BY GERARDO M. BALBONI, M.D., BOSTON.

During the last five years in the Out Patient Department of the Massachusetts General Hospital, one or more cases of hydatid disease have been observed yearly. Up to 1917 twenty-nine cases were studied and reported.¹

In sixteen cases the cysts were located in the liver alone; in five cases other parts as well as the liver were involved, namely, the peritoneal cavity twice; omentum, lung, and kidney once each; in the other eight cases the cysts were found in the brain, heart and pericardium once; kidney twice, peritoneum once, gastro-hepatic omentum once and retroperitoneum twice. There were no cases of hydatid cysts primarily of the lung. Since then two cases of the lung have been observed; one a unilateral cyst of the right lung, the other multiple cysts of both lungs.

These two patients came to the Out Patient Department principally for cough and bloody sputum.

One of these cases is of considerable interest on account of having multiple echinococcus cysts of both lungs with a probable cyst of the kidney. A similar case has recently been reported.²

Cranwell and Vegas in their reported statistics mention two cases of double cysts of one lung; one had two cysts of the right lung, the other had two cysts of the left lung, found at autopsy. Recently Alfredo Buzzi³ reported a sixteen-year-old boy with two cysts of the right lung. He also mentions a case of Araz Alfaro⁴ with multiple cysts of the right lung and a cyst of the left lung revealed by the x-ray and confirmed at autopsy.

It has always been thought by observers of the disease that the liver is the chief seat of the disease. Of late years many more cases of echinococcus cyst of the lung have come to light, due to the more extensive use of the x-ray in the study of chest conditions. As a rule the disease is one-sided and runs a chronic course.

The right lung is more often affected than the left. The most frequent seat of the disease is the middle portion of the lung from the fourth

to the eighth rib, with a tendency to occur lower down. The highest location in the lung has been the axillary region, no case having been reported at the apex. The most common seat is at the periphery of the lung, and cases have been reported adherent to the pleura. If the cyst is located at the periphery of the lung the physical signs are more important than if centrally located. The increase in the size of the hydatid cyst of the lung is not subject to any rule, and the elastic pulmonary tissue accommodates itself to the morbid condition without any reaction for months, and sometimes years.

Hydatid of the lung occurs in two forms: the closed and the open cyst. The open cyst is that which has ruptured into a bronchus or into the lung structure. The expulsion of part or the whole of the contents of the cyst may take place; infection of the cavity occurs, expulsion of purulent material results, sometimes with hemorrhage and severe shock from the absorption of cyst contents. If exit is blocked there result the symptoms of absorption of septic material. Membrane, vesicles and scoleces have been found in the expectorated material of a ruptured cyst. The contents of the cyst may be clear fluid or purulent material. Taubenschlag² has seen as many with clear fluid as purulent. When the cyst ruptures into a bronchus the membrane may undergo degenerative changes from infection of the cavity. Spontaneous cure of the cyst is very rare. This may come about by the death of the hydatid or from rupture of a cyst into a bronchus with the expulsion of the fluid and membrane, subsequent calcification and cicatrization of the cavity. Navarro³ has reported a case of spontaneous cure of hydatid of the lung in a child five years of age.

Briefly stated the symptoms may simulate any pulmonary infection. The symptoms vary; not until the cyst ruptures or the lung becomes inflamed or congested will the patient be conscious of any trouble. Trauma may be the predisposing factor, as in Case 2. Cough, pleuritic pains, expectoration of bloody or clear sputum, not uncommonly a frank haemoptysis. Bloody sputum is a frequent occurrence⁴. Dyspnoea is an inconstant sign. There may be loss of weight and strength, rarely fever unless the cyst has ruptured and become secondarily infected.

Eosinophilia has rarely been present in any of the cases studied, and when present is of negligible value. The complement-fixation test is confirmatory⁵, but when negative does not rule out the disease, as a dead cyst will give a negative reaction as in one of the present cases. Then again the test is not always available. The x-ray is our chief aid in the diagnosis, especially in the closed cyst. Exploratory puncture of the cyst is inadvisable, as sudden death may occur from the rupture of the cyst or from a severe haemoptysis⁶. The cyst fluid has been

evacuated and 1-1000 bichloride solution injected with negligible result.

The x-ray findings may be divided into three distinct pictures: 1st—Closed cysts, which occur as dense circular or oblong, sharply defined areas of increased density within the lung field. The dull area is of even density throughout and the surrounding lung tissue is normal in appearance. The respiratory movements of the diaphragm are only slightly affected and the mediastinum is not involved. 2nd—Open cysts, which may be sub-divided into those which have ruptured into a bronchus and those which have ruptured into the surrounding lung. In the former, the appearance is the same as in closed cysts, excepting that the involved area is of diminished instead of increased density, the appearance suggesting a large cavity with sharply defined borders.

When rupture occurs into the lung structure the appearance closely resembles that of lung abscess. The borders of the lesion are no longer sharply defined and the pleura may be involved, producing a marked limitation of the respiratory excursion of the diaphragm on the affected side.

CASE 1. A. A. 22. Single, Greek. Farm hand. In the U. S. five years; admitted to O. P. D. February 17, 1917.

Chief complaint. Cough, pain in chest, and blood in the sputum.

Present illness. About one and one-half years ago, after slight exertion, he coughed up a teaspoonful of bright red blood, having had a cough six months previous to this. Again, about one year ago, coughed up a glass full of bright blood (one-half glass at a time) after very little coughing. He then stayed in bed the next three months and had bloody sputum every day in streaks and clots; no large hemorrhage. At the end of that time he began to work again and had a little bloody sputum every three or four weeks. One month ago he coughed up one tablespoonful of fresh blood, but none since. During the past one and one-half years, has had only slight cough, mostly in the morning, raising from two to three teaspoonfuls of sputum throughout the day. He felt well, was able to work without feeling tired, and had a good appetite. Has lost some weight and has had no night sweats. Three or four days ago felt tired, unable to work, and had a true chill late the next evening and felt feverish. Some pain in right front chest on coughing. No expectoration of clear fluid.

Past illness. Definite illness at sixteen years. In bed for six months; pain all over abdomen and in the back. Amputation of middle and fourth fingers of the right hand by machine three years ago. In Sparta, worked on a farm. No sheep, one dog.

Physical examination. Well developed and nourished. Mouth and teeth good. No glandular enlargement. *Chest* well developed, expansion equal. *Lungs.* Dullness at right base, posterior

and anterior, with diminished breath sounds and whispered breath, absent tactile fremitus from angle of scapula downward. *Heart*, Negative. *Abdomen*. Slight tenderness over liver, which is palpable, otherwise negative. *Spleen*, not felt. *Reflexes*, normal. *Sputum*, negative; blood smear, normal; Wassermann, negative; echinococcus fixation, negative; urine, negative.

X-ray examination by Dr. G. W. Holmes. The definite outline of a round, dull mass can be seen at the right base, apparently somewhat nearer the front than the back of the chest; it is about the size of a grape fruit and its lower border is lost below the dome of the diaphragm. It does not move with ordinary respiration, but can be displaced somewhat with forced respiration. It is of an even density throughout and its borders are sharply defined. The heart is not displaced.

Operation, Dr. W. Whittemore. Thoracotomy with excision of rib for cyst of the lung. One-fourth of seventh and eighth ribs excised below angle of scapula. Intercostal muscles tied and removed. Pleura opened. It was somewhat thick. Many thin adhesions found between pleura and firm mass in right lower lobe. Diaphragm somewhat below this. Mass sutured to parietal pleura. Incision made in mass, one inch deep, which seemed to go through lung tissue. Needle inserted one inch further. Small amount of clear fluid found. Patient began to pass clear fluid through nose and mouth. Finger dissection into mass opened up a large cyst filled with clear fluid. About 1,500 cc. clear fluid evacuated. No small cysts or hooklets found. Cigarette drain to cavity. Considerable drainage of clear fluid.

Pathological report. A small fragment from the wall of the cyst, showing on microscopic examination a bit of lung whose alveoli are compressed with fibrosis and small round cell infiltration of the connective tissue. There are numerous areas of hemorrhage and some of the alveoli are filled with large cells choked with brownish pigment. There is no evidence of echinococcus. Chronic inflammation.

December 11, 1917. Report from cyst fluid.

Specific gravity, 1.012. Protein, 1.05%. Sugar, 0.055%. Chlorides, .74%.

Creatinine, 0.56 milligrams per 100 c.c. fluid. Urea nitrogen 15 milligrams per 100 c.c. fluid.

Discharged relieved to O. P. D.

January 1. Very slight discharge. Still pain in right costal margin.

January 6. Patient well, wound clean and solid, discharged.

Re-enters hospital September 19, 1919.

Present illness. Since leaving the hospital the patient has continued to cough, especially in the early morning and at night. Still raises small amount of blood, some times bright, but usually dark. No big hemorrhage. Dull localized pain in right lower chest since operation. The pain is increased by coughing. The patient has been working on a farm up to ten months ago, when the pain became too severe to continue work. He

has had no other illness since operation and has not lost weight, but feels weak.

Physical examination. *Thorax*. Some limitation of motion of the right base. *Lungs*. Dullness from seventh rib, right back, extending forward to front at fifth rib. Absent tactile fremitus. Diminished to absent whispered voice and vocal fremitus, also breath sounds diminished. No râles. Slight area above this with increase of tactile fremitus, vocal fremitus and breath sounds. No râles. On the left, dullness in the base from the ninth rib. *Heart*, normal.

Operation by Dr. Whittemore, September 24, 1919. Thoracotomy for recurring echinococcus cyst. Gas oxygen anaesthesia. Incision about 10 cm. long made in scar of old thoracotomy wound and rib resected for about 6 inches. Lung found to be adherent to costal pleura. A large tumor mass presented in lung. On opening into this it proved to be a large cyst and a considerable amount of clear fluid was evacuated. Several large fragments of cyst wall were removed, the cavity was packed with gauze and the wound partially closed.

During the first few days after operation there was considerable drainage of a clear fluid. On the fourth day the packing was removed and the following day the remainder of the cyst was expelled through the operative wound. The wound healed very promptly following this, and in three weeks it was entirely healed. The patient had an uneventful convalescence.

Pathological report. Irregular pieces of cyst wall which show smooth, pearly white surface and which have an elastic consistence. No hooklets can be found on fresh examination. Microscopic examination shows a laminated membrane without cellular structure. The gross or histological appearances are in every way consistent with echinococcus cyst.

CASE 2. P. P. Age 25, white, Greek, single. Laborer in cotton mill; in the U. S. five years; admitted to O. P. D. Sept. 24, 1919.

Chief complaint. Pain in the chest and cough with blood in the sputum.

Present illness. About two years ago was hit on the right side by a piece of iron which fell on him. He was taken to a hospital at Youngstown, Ohio, where he stayed four months and was two months in bed. He was treated medically. At this time he began to cough a lot, often raising bloody sputum. He felt fairly well after leaving the hospital and the cough left him. About six months later cough and hemoptysis returned with pain in the right chest. For the last seven months has not been able to work because he felt sick, raised blood off and on, had pain in the right side and coughed much. Sometimes he has had pain in the left side also. Appetite, poor. Bowels, regular.

Past history. Always well up to present illness; was shepherd in Greece, with dogs associated with him. Weight at present, 150 pounds; two years ago, 170 to 175 pounds.

Physical examination. Well developed and nourished. Skin clear, cheeks flushed, head negative; sclerae clear, pupils equal, regular; tongue coated, throat and tonsils negative; neck negative; chest, well developed; expansion left side greater than right; heart normal in size and position, sounds regular, good quality, no murmurs; lungs, *right chest* dull below spine of scapula almost to flatness, with râles and bronchial breathing, dull in axilla. *Left chest*, râles in lower one-half, with some bronchial respiration; spine negative, no costo-vertebral tenderness; abdomen soft and tympanitic, no masses, spasm or tenderness. Genitals negative, no hernia. Extremities, negative. Reflexes, normal. Blood, white blood corpuscles 7800; red blood corpuscles 7,296,000; 6,896,000; Hgb. 100%; stained specimen, reds normal, platelets normal, but increased. *Poly. 78; cosin. 5; mast 1½; lym. 5½; L.M. 11;* Stools, normal; no parasite or ova. Wassermann negative. Echinococcus fixation test strongly positive.

Sputum. Specimen is mucopurulent and shows no evidence of hooklets or membrane. It is negative for T. B. and shows no characteristic bacteriological finding. Urine amber, clear, acid 1028, albumen 0, sediment 0.

X-ray by Dr. George W. Holmes. In the left chest, below the fifth rib, there is an area of increased density, 4 cm. in diameter; it is round and of even density, with sharply defined borders.

When the position of the tube is changed, overlying it there is a ring-like shadow of diminished density which changes its relation, suggesting a different plane to the dense shadow. Neither reaches the periphery. Similar slightly larger process is seen in the right lung below the fourth rib, with involvement of lung structure.

February 16, 1920. X-ray. Oxygen inflation of abdomen. Appearance in chest much the same as in previous notes.

It is possible to see distinctly the outline of the liver and spleen. They appear to be normal in size and shape; just below the lower margin of the liver there is a round, dense mass, which is apparently connected by a band of adhesions to the abdominal wall.

There is a ring-like shadow in the left kidney, having all the appearances of an echinococcus cyst.

Under the direction of Dr. George W. Holmes, from October 3, 1919, to May 15, 1920, the patient received nine x-ray treatments from two to four weeks intervals, with no improvement in the symptoms, or change in the x-ray findings, nor was there any alteration in the fixation test taken on three different occasions.

When the patient was last seen in May he still complained of an irritative cough, occasionally blood-streaked sputum, pains on both sides of the chest and left kidney region. Tried to work part of the day, but tired easily.

REMARKS.

Echinococcus cyst of the lung is one of the conditions to be thought of and ruled out in cases of pulmonary disease with bloody sputum or frank haemoptysis, especially among the immigrant classes from continental Europe and Asia Minor. The disease is common in South America, Australia, and New Zealand.

The x-ray is our chief aid in the diagnosis, especially in the closed cyst of the lung, and the complemental fixation test when positive is confirmatory, but not essential. Of course the finding of hooklets in the sputum will make the diagnosis, but the cyst will then have ruptured into a bronchus.

TREATMENT.

There is no medical treatment. X-ray treatments may be tried. It had no effect in Case 2. Salvarsan has been tried¹, with no apparent result.

Whenever possible, surgery is the treatment.

STUDIES IN PANCREATIC FUNCTION. ENZYME CONCENTRATION OF DUODENAL CONTENTS AFTER THE INGESTION OF PURE FOODSTUFFS AND FOOD MIXTURES BY NORMAL MEN.

BY C. W. MCCLURE, M.D., BOSTON, AND
A. S. WETMORE, BOSTON.

[From the Evans Memorial, Research Department of the Massachusetts Homeopathic Hospital.]

THE present communication is a report of the results derived from a study of enzymatic activities of duodenal contents. The duodenal contents were obtained from normal young men after feeding pure carbohydrate, protein or fat, both alone and in various combinations, and also after the ingestion of certain food mixtures to be described later. The purpose of the study was to compare the effect of the various types of foodstuffs on the relative amounts (concentrations) of enzymes present in duodenal contents, as ascertained by estimation of the degrees of enzyme action; and by the

same method an attempt was made to determine the relative amounts (concentrations) of enzymes developed at various periods during the time the stomach was emptying itself of food.

Important studies on the rôle of the pancreas in intestinal digestion begin with the work of Claude Bernard¹ in 1856. This observer presented detailed evidence of his claim that the pancreatic juice was of great importance in the process of digestion. But the truth of Bernard's contention was not appreciated for many years, and the physiologists of his time, unable to confirm his observations, opposed the view that the pancreatic secretion played an important rôle in digestion.² The rôle of the pancreas in digestion remained unsettled until the studies of Pawlow,³ Pratt, Lamson, and Marks,⁴ and McClure and Pratt⁵; although much important work on the digestive function of the pancreas was reported by other observers between the years 1890 and 1911.⁶ Pratt, Lamson, and Marks⁴ found that excluding pancreatic secretion from the gut of dogs was immediately followed by the lack of absorption of gross amounts of fat ingested by the animal, and that this failure of absorption remained constant. These observers were able to demonstrate that technical errors accounted for contradictory results obtained by various workers. McClure and Pratt⁵ confirmed the observations of Pratt, Lamson, and Marks, and also demonstrated that depancreatized dogs absorbed from 10 to 50 per cent. of nitrogen and from 17 to 50 per cent. of the fat ingested. Further, they proved that presence of pancreatic tissue in an animal's body is not necessary for the absorption of the products of intestinal digestion, as was held by Lombroso.⁶

The rôle of the pancreas in digestion as demonstrated by the classical work of Pawlow is admirably presented in the well-known book entitled, "The Work of the Digestive Glands". Pawlow worked with dogs, in which animals he produced the fistulae which bear his name. By means of a fistula he was able to obtain pure pancreatic secretion. In this secretion, obtained after feeding meals consisting essentially of protein, fat or carbohydrate, the activities of the various types of enzymes were studied. From these studies Pawlow concluded that the kind of food eaten called forth an increase in the secretion of the enzyme specific for that particular type of food; i.e., protein food caused the secretion of a predominant amount of trypsin, carbohydrate food of amylase, etc.

In 1902, Bayliss and Starling⁷ believed they proved the presence in the intestinal mucosa of a substance called "prosecretin". This "prosecretin" is thought to be converted into "secretin" by the action of hydrochloric acid coming from the stomach. The "secretin" thus formed is believed to be carried through the blood stream to the pancreas, and after reaching that organ to excite its external secretion. But as is pointed out by von Fürth⁸, various substances, such as

cholin, are present in the duodenal mucosa, which have the same action on the pancreas as has "secretin". For this reason von Fürth concludes that until much more is found out about the chemical nature of "secretin," its actual existence remains unproved. Furthermore, nervous control of the pancreas may possibly be important in stimulating its external secretion.⁹ Therefore, it is evident that the status of the factor or factors stimulating the secretion of the pancreatic juice is not well established.

All of the work discussed in the foregoing paragraphs has been carried out on lower animals. Just how much of this work is applicable to man can only be determined by actual observations on human subjects. However, there is much pathological evidence confirming the importance of the external secretion of the pancreas in digestion in man; for example, exclusion of pancreatic juice from the intestines in man is known to be accompanied by marked disturbances in the digestion and absorption of food. But much less is known about the character of pancreatic juice secreted by the human pancreas during digestion. Various investigators have attempted to repeat Pawlow's experiments on human subjects with pancreatic fistulae. These subjects have, however, with one exception, been in such pathologic states or the pancreatic secretion obtained has been so contaminated by material from the intestines that interpretation of experimental results has been problematic. Wohlge-muth¹⁰ was fortunate enough to get pure juice from a human subject with a traumatic pancreatic fistula. Other than for the presence of the fistula, the subject was in normal physical condition. Wohlge-muth repeated the experiments on this subject which Pawlow had carried out on dogs. The results obtained are as follows: The ingestion of food consisting largely of fat brought about pancreatic secretion showing the greatest degrees of all types of enzyme action, while the secretion following a carbohydrate meal showed the least. On the other hand, carbohydrate meals were followed by the secretion of the largest amounts of pancreatic juice, while fatty food produced the least. Thus the results of Wohlge-muth's observations showed the existence of a relation between the kinds of food-stuffs ingested and the amounts of pancreatic juice secreted, and also, the degrees of enzyme action found in this juice. However, no relation was demonstrated between the type of food-stuff fed and the degree of activity of the enzyme specific for that kind of food, as was found by Pawlow in his work on dogs. In this connection it is well to emphasize that the methods for estimating the degrees of enzyme action used by Pawlow, Wohlge-muth, and others, are subject to various errors, so that interpretation of results obtained by their use are open to serious criticism; as has been discussed in a former communication.¹¹ Nevertheless, their results show that the secretion of pancreatic juice during

digestion is in some way governed by the food ingested.

The results of the work outlined in the foregoing discussion permit the following conclusions: 1. Ingestion of food is followed by the secretion of pancreatic juice; but the exact mechanism by which the secretion is stimulated is not established. 2. The external secretion of the pancreas plays a most important rôle in digestion.

While the work outlined above has yielded much of great importance, the methods used have not permitted the study of the conditions under which intestinal digestion actually occurs in living man. It is generally accepted that the end-products of intestinal digestion in man are the same as those in the lower animals; that is, carbohydrates are converted into monosaccharids, fats into soaps, and proteins into amino acids, and that these end-products are absorbed as such. But it should be noted that it was not until the comparatively recent work of Folin,¹² and of Van Slyke¹³ that the absorption from the gut of the end-products of protein digestion was established.

There are available but few studies on the physical and chemical conditions under which intestinal digestion occurs in man. In fact, many of the conditions affecting enzyme action were not established until the publication of the work of Sörensen¹⁴ as late as 1909. This investigator showed that enzyme action was dependent on the hydrogen ion and buffer conditions, as well as those of temperature, under which the enzyme was placed. Practically the only studies on the physical chemistry of intestinal digestion in the living, normal, human subject are those of McClendon *et al.*,¹⁵ and the studies of McClure, Wetmore and Reynolds.¹⁶ Hydrogen ion concentration determinations published by these investigators show that after the ingestion of a mixed diet the pH of duodenal contents of normal man varies in the immediate neighborhood of 4 to 7. McClure, Wetmore and Reynolds¹⁶ have devised methods for the estimation of degrees of enzyme action of duodenal contents which conform to the present-day conception of the physical chemistry of enzyme action, and (a) have made some studies¹⁶ on the physical character and enzymatic activities of duodenal contents obtained from normal young men. The purpose of the latter studies was to devise a procedure for obtaining duodenal contents which would permit the establishment of a normal for the various types of enzyme activities, for use in certain clinical studies. Incidentally, however, it was found that the ingestion of different types of food brought about duodenal contents showing rather characteristic degrees of viscosity, varying in color and consisting very largely of liquid containing but very small amounts of the food originally eaten.

Further studies on the details of physiology of intestinal digestion in normal man were considered important; because only by such knowl-

edge can those processes of pathologic physiology of abnormal gastrointestinal conditions be ascertained which are of importance in clinical medicine. For this reason the present study of the duodenal contents of normal young men has been made.

PROCEDURE.

The subjects chosen for the study were normal young men who gave no history of gastrointestinal derangement. The subjects were instructed to eat a light supper the evening before an experiment, to drink only water during the evening and to ingest nothing after midnight. The following morning the Rehfuß gastroduodenal tube was passed on the empty stomach and without the aid of water. The metal tip was allowed to pass through the pyloric sphincter and as far as the second portion of the duodenum; its position being ascertained by means of fluoroscopic observation. The subjects then reclined on the right side and the duodenal contents were collected either (a) both before and after the ingestion of food or (b) only after the ingestion of food. The contents were siphoned off.

Enzymatic activities were estimated by the methods developed by McClure, Wetmore and Reynolds.¹¹ In these methods proteolytic activity is estimated by allowing duodenal contents to act on a solution of soluble casein. The casein not affected by the proteolytic enzyme is precipitated by means of metaphosphoric acid solution. The index of proteolytic activity is taken to be the number of milligrams of nitrogen not precipitated by the metaphosphoric acid. This nitrogen is determined by an adaptation of the method of Folin and Wu for the determination of nonprotein nitrogen in the blood. Amylolytic activity is estimated as the number of milligrams of glucose developed by the action of duodenal contents on a solution of soluble starch. The index of amylolytic activity is taken to be the total number of milligrams of glucose developed, as determined by the method of Folin and Wu for the determination of sugar in the blood. Lipolytic activity is estimated by allowing duodenal contents to act on a true emulsion of cottonseed oil and determining the amount of acidity developed by titrating with tenth normal NaOH solution. The total number of c.c. of N/10 NaOH necessary to neutralize the acidity developed is used as the index of lipolytic activity. The duodenal contents and the reagents used must be controlled for the presence of nitrogen not precipitated by metaphosphoric acid, for copper reducing bodies and for acidity.

The pure foodstuffs used were arrowroot starch, edestin,* casein and olive oil. The food mixtures were (a) 300 c.c. of a mixture of milk, water, and cottage cheese and (b) 300 c.c. of 20 per cent. cream. The food mixtures were mixed with 40 gms. barium sulphate, which allowed

* The preparation of edestin was furnished by the Arlington Chemical Company, Yonkers, N. Y., whom we thank for their cooperation.

their behavior in the stomach and duodenum to be observed through the fluoroscope.

Duodenal contents may be obtained by means of the duodenal tube, either with or without the use of aspiration. For purposes of description the collection of contents without the use of aspiration is called siphonage. By either method the flow of duodenal contents through the tube was found to be intermittent, issuing in jets at intervals varying from a few seconds to several minutes. By means of the fluoroscope it was determined that the jets occurred coincidentally with the presence of peristalsis in the duodenum, while in the absence of peristalsis only a few drops or no fluid at all were obtained. These observations indicate that the flow of duodenal contents is dependent on an increase in intraduodenal pressure; and for this reason aspiration has no advantage over siphonage. In the work here reported duodenal contents were collected by siphonage.

The enzymatic activities of 20 specimens of fasting duodenal contents were studied. These specimens were collected from six subjects over periods of thirty minutes. The results obtained, together with the quantities and physical character of the duodenal contents, are outlined in the following table (Table I).

Study of the table shows that proteolytic activity varied from 1.2 to 5.0 mgms. of nonprotein nitrogen, lipolytic activity from 0.0 to 2.7 c.c. of N/10 NaOH, and amylolytic activity from 0.3 to 6.7 mgms. glucose. The quantities obtained were from 15 c.c. to 58 c.c. in 15 specimens; while in two specimens 2 c.c. and in one 135 c.c. were collected. All the specimens were of very slight viscosity, and lightly stained some shade of yellow by the presence of bile, except three. Of the three exceptions noted, two were more deeply bile-colored and moderately viscid, and one was fairly viscid and partly light yellow and partly dark yellow in color.

After the ingestion of food substances in volumes of 50 c.c., collection of duodenal contents was divided into three stages, as follows:

1. From immediately after the ingestion of the food substance up to the time the duodenal contents became markedly darker in color (due to bile); *the first stage of collection.*
2. Then over the period of the succeeding hour; *the second stage of collection.*
3. Then over the period of a second hour; *the third stage of collection.*

Study was made of duodenal contents ob-

tained during the *first stage of collection*. A total of thirteen duodenal contents from six subjects was studied and the findings outlined (Table II).

The findings outlined in the above table show that immediately after the ingestion of pure food substances in volumes of 50 c.c., the color and viscosity of the duodenal contents remained similar to those of the fasting contents. But after the lapse of periods varying from 9 to 32 minutes, and 45 minutes in one subject not noted in the table, an abrupt change to a markedly deeper bile color occurred. Before this change in color took place, if casein, edestin or oil had been ingested, food appeared in the duodenal contents. The presence of food was noted either immediately after its ingestion or within a period of 20 minutes, but the change in the color of the bile did not occur for from 7 to 32 minutes after the initial appearance of this food in the duodenal contents. As far as can be judged, there was no increase in the quantities collected over those obtained from the fasting duodenum. The proteolytic activity varied from 0.8 to 4.3 mgms., the lipolytic from 0.0 to 2.2 c.c., and the amylolytic from 0.0 to 3.1 mgms. These variations are comparable to those found in the fasting contents. So that the duodenal contents collected from immediately after the ingestion of food up until the abrupt change to a deep bile color, and those obtained from the fasting duodenum are comparable except for the presence of food in the former.

Studies were next made on duodenal contents collected during the second hour after the change from pale yellow to a deep bile color occurred; *i.e.*, the *third stage of collection*. The results obtained are outlined (Table III).

Study of the table shows that the specimens were some shade of light yellow, with the exception of two specimens which were dark brown. All specimens were moderately viscid but three, which were slightly so. Food was present in three of the specimens. Proteolytic activity varied from 1.2 to 5.5 mgms., lipolytic from 0.6 to 3.0 c.c., and amylolytic from 0.1 to 4.3 mgms. These findings are comparable to those obtained in the fasting duodenal contents, and in those collected immediately after the ingestion of food, except for the increase in viscosity, and the occasional presence of food. (The findings will be discussed later.)

The collection of duodenal contents for the first hour after the abrupt change to dark-colored bile occurred is called the *second stage of collection*, or the first hourly specimen. The enzymatic activities, physical character and quantities of duodenal contents obtained during this second stage of collection are outlined in the following table (Table IV).

All duodenal contents outlined in the above table were deeply bile colored, in which respect they differed from the great majority of duodenal contents previously described in Tables I, II, and III. The viscosity was much greater than was found in contents derived from the fasting duodenum or collected immediately after the ingestion of food, but not more so than was usually found in specimens obtained during the third stage of collection. The amounts of duodenal contents collected varied from 42 c.c. to 270 c.c. Proteolytic activity varied from 2.7 to 5.7 mgms., lipolytic from 1.0 to 4.4 c.c., and amylolytic from 2.5 to 4.5 mgms. of glucose. Comparison of the figures with those represent-

TABLE IV.

ing the minimum and maximum enzymatic activities of the fasting duodenal contents (Table I), and of those obtained during the first and

third stages of collection (Tables II and III) are given in the following table (Table V).

TABLE V.

Minimum and maximum degrees of enzymatic activities of fasting duodenal contents and of contents obtained during the first, third and second stages of collection.

Time of collection of duodenal contents	Enzymatic activity					
	Proteolytic in mgm. WPN.		Lipolytic in c.c. N/10 NaOH		Amylolytic in mgm. glucose	
	Min- imum	Max- imum	Min- imum	Max- imum	Min- imum	Max- imum
Fasting duodenum	1.2	5.0	0.0	2.7	0.3	6.7
First stage collection	0.8	4.3	0.0	2.2	0.0	3.1
Third stage collection	1.2	5.5	0.6	3.0	0.1	4.3
Second stage collection	2.7	5.7	1.0	4.4	2.5	4.6

The figures in the above table, representing the maximum degrees of enzyme action, show that considerable degrees of activities may be present in duodenal contents collected at any period; while those for minimum action show that activity may or may not be manifested. But the degrees of enzyme activity shown by the figures for minimum action of the various types of enzymes in the duodenal contents obtained during the second stage of collection are much greater than those shown for the minimum action in specimens collected at other periods. The significance of this finding will be discussed later.

Observations were made in order to determine the relative enzymatic activities of fractions of the duodenal contents obtained during the second stage of collection. For this purpose three subjects were fed a mixture consisting of 25 gms. casein and 25 c.c. water. After the dark colored bile appeared the first fractions of duodenal contents were collected over periods of 7 minutes, 15 minutes and 16 minutes; the next over periods of 33, 34 and 15 minutes, and of 45 minutes in one. The results obtained are outlined in the following table (Table VI).

TABLE VI.

Enzymatic activities of fractions of duodenal contents obtained during the second stage of collection after the ingestion of casein.

Subject.	Enzymatic activity			Amt. in c.c.	Period of col- lection in min- utes.
	Pro- teoly- tic in c.c. N/10 NaOH	Lip- oly- tic in c.c. N/10 NaOH	Amy- lytic in mgm. glucose		
Cush.	5.5	4.0	1.0	55	15
	4.0	2.0	1.0	100	33
Wright.	4.7	3.2	1.9	35	16
	3.1	1.2	1.4	50	34
Cush.	1.7	1.8	2.0	1.0	7
	1.1	1.7	1.0	1.0	15
Cush.	1.5	1.4	1.1	1.0	45

Study of the table (Table VI) shows that, in the different fractions of duodenal contents collected from the same subject, the degrees of action of the same type of enzyme did not vary widely, except in the two following instances. The lipolytic activity of the first fraction obtained from subject Ought is twice that of the second fraction; and the amylolytic activity of the third fraction from subject Cush is much larger than those of the first two fractions. None of the figures fall below those given for minimum enzymatic activities of duodenal contents obtained during the second stage of collection as outlined in Table IV. It will be recalled that the second stage of collection began with the appearance of dark-colored bile; therefore, the increase in the flow of enzymes into the duodenum and the beginning of the flow of bile were about coincident.

A synopsis of the results of the foregoing observations is given as follows: Duodenal contents obtained from the fasting duodenum, and during the first and third stages of collection are comparable, except for the greater viscosity of the specimens of the third stage of collection. The enzymatic activities of the specimens vary from little or no activity to considerable degrees of activity. When compared with these specimens, those obtained during the second stage of collection were much darker in color, and the minimum degrees of enzyme action were all much greater. The fractions of duodenal contents collected during the second stage from the same subject showed fairly uniform degrees of activity for each type of enzyme. An increase in the flow of enzymes and bile into the duodenum occurred approximately at the same time.

Pure food substances were used in the study to determine the effects of various foods on the relative concentrations of enzymes present in the duodenal contents, as estimated by degrees of enzyme action. The pure substances were edestin, arrowroot starch and olive oil. When fed singly, 10 gms. of each substance were used; when given in combinations of twos, 5 gms. of each were mixed; when all three were mixed,

3 1/3 gms. of each were used. To each preparation in hot water, forming a gelatinous paste, before it was fed. The results are given in the following table (Table VII).

TABLE VII.
Enzymatic activities, amounts and physical character of duodenal contents derived from pure food substances, fed singly and in combinations.

Subject	Enzymatic activity			Amt. in c.c.	Color	Viscosity	Kind of food ingested
	Proteolytic in 10 c.c. 8/10 N.S.	Lipolytic in 10 c.c. NaOH	Amylolytic in 10 c.c. 8/10 N.S.				
Brown	3.9	2.4	4.6	125	very dark brown	Moderate	10 c.c. olive oil
	3.3	1.6	2.4	105	dark brownish yellow	Moderate	10 gm. edestin

	4.7	2.0	3.5	95	dark yellow brown	" "	5 c.c. olive oil and 5 gm. edestin
	5.0	0.7	2.9	55	yellowish brown	" "	6 1/3 c.c. olive oil, 3 1/3 gm. edestin, 3 1/3 gm. starch
Desj.	3.2	1.8	3.6	270	very dark brown	Moderate	10 c.c. olive oil
	3.4	1.5	3.6	140	dark brownish yellow	" "	10 gm. edestin
	3.0	1.0	3.3	100	yellowish brown	" "	10 gm. arrow root starch
	5.4	1.2	3.1	110	yellowish brown	" "	5 gm. arrow root starch, 5 c.c. olive oil
	4.5 2.1	0.0 0.6	2.7 2.1	90	brownish yellow	" "	5 gm. arrow root starch, 5 gm. edestin

As outlined in the above table, the viscosity of the various specimens was about the same. After the ingestion of oil the duodenal contents were very dark green in color, after edestin brownish yellow and after starch yellowish brown. Thus, each pure food substance gave rise to a characteristic color in the duodenal contents. The mixtures of those foods which contained oil gave rise to duodenal contents of yellowish brown color, while the contents from the starch and edestin mixture were brownish yellow. The largest quantities of duodenal contents were collected from the oil, the next largest from the edestin, less from the starch and the smallest amounts from the food mixtures. Lipolytic activity was greatest in duodenal contents derived from the oil, next greatest in those from edestin and least in those from the starch; while in the contents from the mixtures of oil and starch and of oil and edestin lipolytic activity was of average amount. Thus, in these two subjects the ingestion of oil was followed by the greatest degree of action of the enzyme specific for fat. But this specific relation did not hold for the proteolytic and amylolytic activities after the ingestion of the edestin and starch. In general the figures representing proteolytic and amylolytic activity are comparable in the different specimens of duodenal contents derived from the two subjects. After the ingestion of the mixtures of olive oil, edestin and starch and of

starch and edestin lipolytic activity was reduced, and on one occasion absent.

Further comparative studies of enzymatic activities of duodenal contents were made on three subjects after the ingestion of olive oil and of casein. For this purpose the subjects were fed a mixture of 25 c.c. olive oil and 25 c.c. tap water and a mixture of 25 c.c. bulk of casein and 25 c.c. tap water. The results obtained are outlined in the following table (Table VIII).

TABLE VIII.
Enzymatic activities of duodenal contents derived from olive oil and from casein during the second stage of collection.

Subject.	Enzymatic activity.			Kind of food ingested.
	Proteolytic in 10 c.c. 8/10 N.S.	Lipolytic in 10 c.c. NaOH.	Amylolytic in 10 c.c. 8/10 N.S.	
Ought	4.	2.0	1.0	Casein
	5.7	1.5	2.6	Olive oil
White	4.4	3.2	1.4	Casein
	6.0	4.8	4.3	Olive oil
Cush	3.5	1.4	3.5	Casein
	3.5	3.3	4.3	Olive oil

Study of Table VIII shows that duodenal contents derived from oil presented greater degrees of lipolytic action than those derived from casein. These findings confirm those discussed above (Table VII) which show that lipolytic activity is greater in duodenal contents derived from olive oil than in contents derived from casein, edestin and starch meals.

Comparative studies of the degrees of enzymatic action were made in duodenal contents derived from the fasting duodenum, after the ingestion of tap water and after drinking cornstarch solution. For this purpose the fasting contents were collected over periods of thirty minutes, then 50 c.c. of tap water were given and the contents collected over periods of 40 to 60 minutes, and after this 50 c.c. of 0.5 per cent.

cornstarch solution were ingested by two of the subjects and the duodenal contents collected for one hour. After the ingestion of water, by the three subjects to whom no cornstarch was given, the duodenal contents were collected for two hours; in fractions of one hour each. The enzymatic activities of the two fractions were similar. The results obtained from this comparative study are outlined in the following table (Table IX). To the table are added the figures representing the enzymatic activities of duodenal contents collected after the ingestion of a mixture of olive oil and tap water. The experiments with the oil feedings were made on days different from those with the fasting duodenum and tap water feedings.

	2.7	0.0	0.0	120	60	50 c.c. 0.5% cornstarch
	5.7	3.5	2.4	100	60	25 c.c. olive oil and 25 c.c. tap water.
White	3.7	1.0	0.8	2	30	Fasting duodenum
	2.0	0.1	0.0	105	45	50 c.c. tap water
	2.3	1.4	0.2	80	60	50 c.c. 0.5% cornstarch
	6.0	4.0	4.3	100	60	25 c.c. olive oil and 25 c.c. tap water.
Brown	5.0	0.5	1.2	18	30	Fasting duodenum
	3.0	1.1	0.9	39	60	50 c.c. tap water, 5 gm. barium sulphate.
	3.0	2.4	4.5	120	55	10 c.c. olive oil and 40 c.c. tap water.
Deeser	1.0	1.1	1.9	25	30	Fasting duodenum
	3.0	0.5	2.0	60	60	50 c.c. tap water, 5 gm. barium sulphate.
	3.2	1.8	3.6	270	63	10 c.c. olive oil, 40 c.c. tap water.

In the above table (Table IX) comparison of enzymatic activities of the contents of the fasting duodenum and after drinking water shows that proteolytic activity was diminished in three and increased in two; lipolytic activity was decreased in two; amylolytic activity was diminished in four and slightly increased in one. In duodenal contents derived from cornstarch proteolytic activity was increased in one and decreased in one and the same held true for lipolytic activity. Thus, after the ingestion of water or weak cornstarch solution the degrees of action

of the various enzymes present in the duodenal contents may be diminished or increased, as compared with the activity of those present in the fasting contents. However, after the ingestion of olive oil degrees of action of all these various enzymes were increased in the contents of each subject. These findings are portrayed in the following table (Table X). To the table are added the minimum and maximum figures for enzymatic activities after the ingestion of casein or edestin by four of the subjects.

The findings in Table X show: 1, that the en-

zymatic activities of duodenal contents derived from water or cornstarch solution are comparable to those present in the fasting contents; and 2, that much greater minimum degrees of enzyme action were present in duodenal contents collected after the ingestion of olive oil, of casein and of edestin.

A study of the enzymatic activities and hydrogen ion concentrations* of duodenal contents

collected over hourly, and in some instances 15 minute periods, was made. The collections were carried out for four hours with each subject. For the purpose of this study five subjects were fed a mixture of milk, cottage cheese and 40 gms. barium sulphate, and two subjects 20 per cent. cream and 40 gms. barium sulphate. Each meal consisted of a volume of 300 c.c. The minimum emptying time of the stomach was about four hours, so that each specimen of duodenal contents was collected while food was passing out of the stomach. Within a few minutes after a subject had ingested a meal, deeply bile colored duodenal contents were returned through the tube; and these contents contained barium and food in easily demonstrable amounts. More or less food and barium were obtained in all the duodenal contents collected after the ingestion of these meals. In three subjects the contents collected during the first hour were fractioned into four parts, each part covering a period of 15 minutes. The results obtained in this series of experiments are outlined in the following table (Table XI).

Study of Table XI shows that the enzymatic activities were generally comparable to those in duodenal contents obtained during the second

* Specimens collected over 15 minute periods.

stage of collection, after feeding the pure food substances (see Table IV). The enzymatic activities of the 15-minute specimens were comparable to those of the succeeding hourly collections, except for the third 15-minute specimens in subjects A and B. These two specimens were grayish instead of yellow in color, which showed a considerable dilution with material from the stomach; and this undue dilution explains the

low degrees of enzyme action present in the specimens. The same type of enzyme varied moderately in the degrees of its action in the different hourly specimens of duodenal contents from the same subject, but there was no regular manner in which the variations occurred; that is, there was no systematic increase in the enzymatic activities from the first to the fourth hours, except for the proteolytic activity in subjects B, and E.

The findings discussed in Table XI show that the enzymatic activities of duodenal contents, as

* Hydrogen ion concentrations were determined by a potentiometer constructed by the authors under the direction of Dr. Bowie, of the Harvard Cancer Commission. Dr. Bowie's quadrant electrometer was used.

estimated under the experimental conditions used, remain relatively constant for each type of enzyme as long as the stomach is in the process of emptying itself of food. From this finding it is inferred that the amounts (concentrations) of the enzymes remained relatively constant.

The hydrogen ion concentration determinations demonstrate that no relation existed between the degrees of acidity of the duodenal contents and the degrees of enzyme action.

DISCUSSION.

Enzymes present in duodenal contents may be derived from the pancreas, from the stomach, possibly from saliva and perhaps from duodenal mucosa. However, the methods used in the work here reported, when applied to the study of enzymatic activities of duodenal contents derived from patients,* show that all but very small degrees of enzyme action are absent when diseased processes have excluded pancreatic secretion from the duodenum. Thus, the enzymes demonstrated by these methods probably originate almost exclusively, if not entirely, in the pancreas. For this reason demonstration of enzymatic activity in duodenal contents indicates the presence of pancreatic secretion; and in the discussion of the work here reported it will be assumed that the various enzymatic activities demonstrated represent the action of enzymes secreted by the pancreas.

In patients* with complete obstruction to the common bile duct it has been found that the absence of bile does not demonstrably influence the activity of enzymes of duodenal contents as estimated by the procedures employed. Furthermore, addition of human bile to duodenal contents did not increase the activities of the enzymes, as demonstrated by the methods used. Theoretically, this is what would be expected with the methods, in view of the physical conditions under which the enzymes act. Because of these findings it is considered that the presence of different amounts of bile had a negligible influence on the activities of the various enzymes, as determined by these methods.

The term "fasting" duodenal contents designates the contents obtained from the duodenum about fifteen hours after the last ingestion of food and about nine hours after the last drink of water. But in taking the duodenal tube subjects swallowed much saliva; and it is also well known that the normal fasting stomach contains more or less acid secretion, cellular debris and mucin. Undoubtedly the stomach throws these materials over into the duodenum, so that a truly fasting state of the stomach and duodenum was not present during the course of the experiments here reported. Just what rôle the presence of these materials, or of the tube, in the duodenum played in the production of the presence of enzymes in the duodenal contents, was not deter-

mined. All that can be concluded is, that, under the experimental conditions here reported, proteolytic and amylolytic activities were always present in duodenal contents; while lipolytic activity was occasionally not demonstrable.

Enzymatic activities of duodenal contents obtained during the third stage of collection (Table III) were generally comparable to those obtained in fasting duodenal contents (Table I). It is considered that not infrequently the stomach had emptied itself of food during the second stage of collection; so that during the third stage the contents collected were often fasting contents. However, many observations* show that the normal stomach empties at different rates in different persons; and it was demonstrated that the stomach, during the experiments here reported, was not always empty at the time of the third stage of collection. Thus, at times the duodenal contents collected during the third stage represented the same conditions as were present during the second stage of collection; and under these conditions the enzymatic activities of the third and second stages were always found to be comparable.

It will be noted that the fasting duodenal contents at times showed degrees of enzyme action comparable to those found in duodenal contents obtained during the second stage of collection or after the ingestion of food mixtures of 300 c.c. volume (compare maximum figures of Table V and figures of Table XI with those of Table I). But the fasting contents were relatively undiluted, while those collected after the ingestion of food were diluted with bile and gastric chyme. Amounts of the latter were particularly large after the ingestion of meals of 300 c.c. volume, as judged both by the quantities of duodenal contents collected and the amounts of barium seen to be ejected from the stomach into the duodenum when observed through the fluoroscope. For this reason the enzymatic activities found in duodenal contents during the time the stomach was emptying itself of food represented greater concentration of enzymes than was present in the fasting duodenal contents.

During the second stage of collection the stomach was emptying itself of food, and duodenal contents obtained during this stage showed minimum degrees of enzyme action much greater than minimum degrees demonstrated in duodenal contents collected over other periods (Table V). From this it is concluded: 1, that during the second stage of collection increased concentration of enzymes was present in the duodenal contents; and 2, that during this stage the effect of the ingestion of food on pancreatic activity is shown. In other words, the findings show that the presence of food in the stomach and intestines in some way brings about the stimulation of the secretion of pancreatic juice.

Evidence of pancreatic stimulation was much less pronounced after the ingestion of water or

* Unpublished observations.

* Unpublished observations.

weak cornstarch solution than after the ingestion of foodstuffs (see Table X). Water¹⁷ and cornstarch solution stimulate the secretion of acid gastric juice; so that after their ingestion acid fluid was ejected from the stomach into the duodenum. Because of this it is concluded that something more than the mere ejection of acid gastric contents into the duodenum is necessary to stimulate materially pancreatic secretion.

Not only was it demonstrated that food substances stimulate pancreatic secretion, but it was also demonstrated that lipolytic activity was greatest after the ingestion of olive oil, less after protein and least after carbohydrate (Tables VII and VIII). Furthermore, duodenal contents obtained after the ingestion of oil showed greater degrees of all types of enzymatic activity than did contents derived from protein. This last statement holds true for duodenal contents derived from four of the five subjects on whom these experiments were carried out (Tables VII and VIII). In the fifth subject the duodenal contents showed the greatest degree of lipolytic activity after the ingestion of oil, but proteolytic and amylolytic activities were comparable to those derived from a meal of edestin. Nevertheless, the findings show the existence of a relation between the degrees of enzyme action and the kind of food ingested.

It was found that lipolytic activity was diminished or absent after the ingestion of certain mixtures of the pure foodstuffs (Table IV). There is no reason to doubt that these mixtures called forth secretion of HCl in the stomachs of the subjects. At any rate, it was proved that the food mixtures were ejected from the stomach into the duodenum; and the acid fluid normally present in the fasting stomach would necessarily, also, be thrown over into the duodenum. If HCl were the principal factor in bringing about the secretion of pancreatic juice, it seems strange that at times it would fail to do so in normal persons. On the other hand, it is conceivable that the physical state of foodstuffs mixed with a gelatinous substance like arrowroot starch paste might be such as to render their digestion very slow. As a result little or no pancreatic secretion might be stimulated and only the activity of enzymes already present in the fasting duodenal contents would then be demonstrable. This may be the true explanation of the findings in the duodenal contents derived from the mixture of arrowroot starch, edestin and olive oil and from the mixture of arrowroot starch and edestin (see Table IV).

The findings in Table XI demonstrate: (1) that the enzymatic activities of duodenal contents did not show systematic increase as digestion progressed; from this it is inferred that the relative concentration of enzymes present did not increase proportionately. (2) the findings also show that no relation existed between hydrogen ion concentration (degrees of acidity in the

duodenum) and the concentration of active enzymes in the duodenal contents.

It was found, after the ingestion of pure foodstuffs and the appearance of the latter in the duodenal contents, that from seven to forty-five minutes elapsed before an increase in enzyme action was noted. This observation is most easily made after the ingestion of olive oil and tap water. The oil will be collected constantly over periods varying from ten to forty-five minutes before an increase in enzymatic activities and the change to the dark bile occur. These observations show: (1) that after the appearance of pure foodstuffs in the duodenum there is a latent period before the flow of enzymes and bile is stimulated; while (2) the finding that the flow of bile and enzymes was coincident suggests a common stimulating factor.

During the period of latency four phenomena were probably occurring: (1) an increase in the hydrochloric acid concentration of the stomach contents; (2) the actions of gastric and salivary enzymes on foodstuffs present in the stomach; (3) the action of duodenal enzymes on foodstuffs ejected from the stomach into the duodenum; and (4) the absorption of the products of digestion. What effect increase in gastric acidity, which occurs as digestion progresses, had on duodenal acidity, was determined after the ingestion of milk and cottage cheese and after cream. No effect was found (Table XI). The significance of the absorption of products of food digestion will be discussed later.

The findings: (1) that something more than the mere ejection of acid gastric contents into duodenum was necessary to stimulate demonstrably the secretion of pancreatic juice, and (2) that no relation existed between the degrees of acidity (hydrogen ion concentrations) and the action of enzymes in duodenal contents are evidence that the acidity of duodenal contents was not the essential factor in bringing about the stimulation of the secretion of pancreatic juice. On the other hand, the findings: (1) that food in some way stimulated the secretion of pancreatic juice; (2) that a relation existed between the degrees of enzyme action and the kinds of food ingested; (3) that a latent period existed in which foodstuffs could be digested and absorbed; and (4) that water was a much less potent pancreatic stimulant than food, although water stimulates a normal gastric acidity, present evidence that the products of food digestion are an essential factor in stimulating the secretion of pancreatic juice.

The above interpretation of the findings in the experimental work here reported do not agree with the view of Pawlow, except for lipolytic activity. They do not uphold either the secretin theory of Bayliss and Starling or the hypothesis of a nervous mechanism as the most potent factors in the stimulation of the secretion of pancreatic juice. The remaining most probable possibility is that the products of the digestion of

food are the most important factor in stimulating the pancreas to secretory activity.

The disagreement with Pawlow's contentions may possibly be more apparent than real. In the first place Pawlow worked on dogs; and a pancreatic regulatory apparatus may exist in dogs which is different from that of man. In the methods used by Pawlow for demonstrating enzymatic activity the substrates acted upon by enzymes were placed directly into pancreatic juice. The hydrogen ion and buffer conditions of the various specimens of pancreatic juice may have been such as to give results justifying Pawlow's conclusions. But the physical chemistry of Pawlow's methods is so grossly erroneous that an interpretation of results obtained by them is well-nigh impossible.

The experiments of Bayliss and Starling consisted of intravenous injection into animals of hydrochloric acid extracts of duodenal mucosa. In this way pancreatic secretion was stimulated. But the work of von Fürth clearly demonstrates that it is not necessary to assume the existence of "secretin" to explain this stimulation. This investigator, among others, has demonstrated that various well-known chemical substances normally present in duodenal mucosa will produce such a stimulation. Furthermore, the maceration of duodenal mucosa and its extraction with hydrochloric acid might very well form compounds (due to decomposition of proteins, etc.) similar to those occurring during digestion; such compounds may play a rôle in the stimulation of pancreatic juice when injected into the blood stream of an animal. In other words, the chemistry of the work of Bayliss and Starling was such as not to justify the drawing of far-reaching conclusions from their observations.

Experiments have been repeatedly carried out by the present authors in which water, N/20-HCl, glucose solutions and olive oil have been introduced directly into the duodenum of men. The results were the same as those obtained after the ingestion of these substances by mouth. Certainly these substances were introduced into the duodenum in an inert chemical state, except the N/20HCl. This contradicts the often-quoted statement that such substances do not stimulate pancreatic secretion. From these experiments it was concluded that whenever any harmless liquid is introduced into the duodenum of man intestinal digestion and absorption begin.

The absorption of materials present in the duodenal contents and those coming into the duodenum from the stomach (for in man the introduction of fluid into the duodenum always starts up the ejection of stomach contents into the duodenum, as the authors have repeatedly demonstrated) could explain the often-quoted experiment of Popielski.¹ In this experiment hydrochloric acid solution was placed in the duodenum of one dog, whose blood supply was connected to that of another dog; as a result pancreatic juice was secreted by the latter. The contamination of the original duodenal material

with gastric contents introduces an element of uncertainty, as digestible material thus present would give rise to products analogous to those produced by food digestion. In fact, all the work supporting the "secretin" theory furnishes only indirect evidence of the correctness of that theory; while phenomena urged in its support can all be explained in other ways by using well established facts as a basis.

This discussion is not intended to belittle the excellent work of two such competent experimenters as Drs. Bayliss and Starling. But the purpose is to emphasize that "secretin" remains a hypothetical substance. Furthermore, it should be emphasized that the work on "secretin" has all been carried out on the lower animals, and whether or not the same experimental results would be obtained in man has not been determined.

The principal conclusions reached in the above discussion may be summarized as follows:

1. The findings showed that the presence of food in the human intestines in some way stimulated the activity of the external secretory function of the pancreas. They indicate that the principal factor in producing this stimulation was the absorption of the products of digestion rather than the acidity of the gastric chyme.
2. Lipolytic activity of duodenal contents was always, while proteolytic and amylolytic activities were almost always, greater after the ingestion of olive oil than after the ingestion of protein or carbohydrate food. From this it is inferred that olive oil was a more powerful stimulant to the activity of the external secretory function of the pancreas than were the other types of food.
3. Water was a less potent stimulant of external pancreatic secretion than were food substances.
4. After the appearance of food substances in the duodenum there was a latent period before the flow of enzymes and bile began.
5. The time coincident of the onset of the flow of bile and pancreatic juice suggests a common stimulant.
6. Under the experimental conditions employed the fasting duodenal contents contained both enzymes and bile pigments.

We wish to express thanks to Dr. Lafayette B. Mendel for helpful criticism of the preliminary studies on which this work was based; and, also, to Dr. A. W. Rowe for his valuable coöperation.

Suffolk District Medical Society.

MEETING ON "REHABILITATION."

The Suffolk District Medical Society held a meeting on "Rehabilitation" at the Boston Medical Library on November 22, 1922. The program was arranged by Dr. Hilbert F. Day, and the following speakers took part:

DR. F. J. COTTON, Boston: Reconstruction or rehabilitation, which was brought into prominence by the war, is being carried over into civil life and industry. It is a field the importance of which is just beginning to be recognized and its scope broadened. The problems are similar to those encountered in the war, namely to save the derelicts of industry. Everybody dealing with the subject from the surgical side is impressed with the fact that the cases are due to bad surgery and are avoidable. What we ought to have is a better type of surgery which will make correcting the mistakes of others unnecessary. For instance, cases of fracture of the os calcis which go through the ordinary routine and are crippled, are picked up in the reconstruction work and brought back to normal. Then there are cases of Colles' fracture which often have a permanent partial or total disability. We can handle those cases late and straighten them out very well, although it should be unnecessary. Of course, results obtained late are not comparable to results at the time of injury.

An important part of the work of rehabilitation is bridging the patient over from the time of injury to his return to the pay-roll. The average surgical case receives surgical treatment only and is discharged unfit to go back to work. The medical man should be called in, also the orthopedist, the physiotherapist and the man who knows occupational therapy. We need team work. Take, for example, a man of fifty with a fractured femur or any case requiring a long period of treatment. Such cases are not cases for surgical reconstruction alone but cases for team work rehabilitation. The success of rehabilitation depends on proper team work. This is purely a team work proposition. My own feeling is that we are going

to have institutions for this sort of thing where a man can be taken care of during the period of convalescence with a view to his rehabilitation to industry.

THE STATE INSTITUTIONS.

DR. JOHN H. NICHOLS: In the Industrial Departments of the State Institutions we have the inmates engaged in carpentry, basket making, weaving, mending, farming, etc. The work is assigned; hours of work are fixed. Industrial employers hire men who are 75 percent plus efficient, but men who are only 50 percent efficient are outcasts. It seems to me that the problem of finding a market for their wares is harder than finding work for the inmates.

I would present two viewpoints: The first, the more difficult, is to promote successfully a "back to the country," "back to the farm" movement. Even the cripple insists on going back to the city. On the farm there is always something that the cripple can do and be self-supporting. But now the unfortunates and crippled can scarcely earn a livelihood on the farms in this Commonwealth. Movements for small farms and gardens should be promoted and reclamation of waste land. The physicians could then send patients out on farms for rehabilitation where they could help to raise farm products. We might call them "heliotherapy" farms.

The second viewpoint which especially bears on the problem is a city problem. Why not erect a building in the city for these cripples who are loafing or selling pencils on the street? Call it a service shop or accommodation shop where cripples can go and do repair work and mending and all sorts of light work. Have a building centrally located which could serve as an employment office and as a clearing house for the sale of articles made by cripples.

CERTAIN LEGAL ASPECTS.

JOSEPH A. PARKS, Esq.: Rehabilitation is the biggest problem under the Workmen's Compensation Act, bigger than the matter of compensation. I want to take up the problem of the cripple after he has left the hands of the doctor. He has got stale. Take the case of a man who has lost an arm, a hand or fingers—how are you going to get such a man back into industry? You can't unless you have the whole-hearted support of the employers of labor in this Commonwealth. Few employers are kind enough to employ such men. The result is that the cripple drifts about from job to job, his physical condition getting worse. Employers should coöperate with the Board and with the doctors. The sum of \$7,000,000 is paid out every year for compensation insurance and for doctors' bills, and there is no reason why \$1,000,000 cannot be clipped off that sum by the proper coöperation on the part of employ-

ers, and at the same time have a reduction in the amount of premiums paid. As a business proposition we can demonstrate to employers that an injured workman isn't a liability but an asset and will do just as much work if given an opportunity and the right kind of sympathy. We want the employers of labor in this State to coöperate with us in this great movement.

PHYSIOTHERAPY.

DR. FRANK B. GRANGER, Boston: From a consideration of the civil army of the industrially incapacitated the high lights are: 1. The necessity of team work between the branches of surgery and medicine, including the laboratory social work and occupational therapy; 2. The importance of functional cure or restoration; 3. The economic gain due to shortening the period of disability; 4. The restoration to productive, remunerative work of many who would otherwise be permanently crippled and a burden to the community. All measures of value should be employed. Active exercises, in-door and out-door games, and passive exercise in the form of massage; physiotherapy, hydrotherapy, electrotherapy and heliotherapy—one or more combined where indicated.

Measures used—type of current: 1. Diathermy or internal baking. This modification of the high frequency current is useful where it is desired to secure deep seated effect on the tissues. 2. Ionization—this is analogous to commercial electroplating and is a means of introducing certain chemical salts. 3. Sinusoidal current—this is of value in restoring muscle tone. 4. Galvanism—this is useful for relief of pain and for nerve stimulation. In hydrotherapy the whirlpool bath is efficacious. Instead of medical massage the use of competitive games has proved of value in many conditions such as paralysis, hysteria, neurasthenic states, and certain types of cardiac disease. In fractures use the high frequency current at the time of complete union. In non-union use diathermy. For adherent scars use radiant heat. Arthritis—use radiant heat. Contusions respond to diathermy and to the Bristol coil. Physiotherapy should be carried out under the direction of trained technicians and is a challenge to the various cults.

OCCUPATIONAL THERAPY.

DR. JOHN D. ADAMS, Boston: Occupational therapy is what the name implies—the idea of occupying the patient in the hospital wards in order to hasten his convalescence, restore his function, and mentally restore him to his former state of mind. It is not a diversion but a treatment applied in conjunction with the doctor. What is the present status of occupational therapy? A school was organized in Boston,

graduated 100 occupational therapy aides, girls, who were sent to France, who demonstrated their efficiency. The period of convalescence of the patients over there was reduced 30 percent. The school was perpetuated, a board of managers was organized. These girls, who are students of the occupational therapy school, are taken from all walks of life. An educational standard is required. These girls are taking it up as a means of livelihood. The course is twelve months. Today there are seven well established, well recognized schools in the United States. These girls go into the hospitals and teach the patients the various arts and crafts, among which are toy making, jewelry making, basketry, etc. These girls teach the patients to make these products. What is done with the products? We have established a bureau in Boston on Berkeley Street, where the products are sold. The bureau charges a commission of 15%. A State Society has been organized. Dues are \$3 a year. We have at the present time about 300 members. Our State director, Miss Robeson, sent out questionnaires to all the hospitals in the State. Only 57 replied. Of those 57 only 32 make active use of occupational therapy at the present time.

DISCUSSION.

DR. FRANCIS W. ANTHONY, Haverhill: There are two methods of solving the problem, the ideal and the practical. We have to make our work conform to the practical. The ideal result is economic, functional restoration not necessarily to a point beyond the normal point of the individual. I claim that to determine this we must have more than a knowledge of the man's injuries, more than the surgical or medical picture. We must have a knowledge of the individual and know his mental status. We must know his mental ability, his experiences, his personal reactions, his environment; we must have all that combined with the knowledge of the surgical condition, then we can treat the individual. This means group study which must be centrally controlled. After your study is completed, what can be done for the patient? He may be helped at home, especially if near a central station; he may be helped in a general hospital or in a special hospital. I believe that the best place is a special hospital, a special hospital not under State or national control, especially not politically controlled,—the worst kind of control,—but a hospital especially endowed; that would be the ideal. What is practical? A reference board. There you enter medical politics. It seems to me that the thing must now function through the Accident Board. The reference board, taking the case up, would decide where to send the case to obtain the best results.

THE INDUSTRIAL SIDE.

DR. FRANCIS D. DONOGHUE, Boston: When Mr. Parks says that \$1,000,000 can be clipped off in premiums, I want to make it clear that he means \$1,000,000 paid by the employers and not \$1,000,000 off the doctors' bills. The Compensation law is a compromise between the ideal and the possible. The insurance companies have seen that adequate medical treatment is the best kind of compensation. I have no doubt that accident cases are treated better than the average hospital case. The family doctor should come in. The compensation case is treated two weeks and, if it is an unusual case, longer, and the insurance companies usually pay for a longer medical treatment. The case that comes to the Industrial Accident Board is 40 years old, the average case, and our replacement doesn't require elaborate therapy because the men want quick replacement and not rehabilitation.

CERTAIN MEDICAL AND MENTAL ASPECTS.

DR. E. K. BURBECK (ms.): The physician should understand more than pharmacology; he should know functional diseases, inherited tendencies, effects of environment and development. Inherited tendencies we cannot change. To understand childhood training and environment is to understand some mental conditions in adult life. From the mass of endocrinology stands out the effect of secretions on the body growth. Faulty bodily mechanics has been shown to produce definite medical defects in the child as well as in the adult. Deficient muscular tone can be counteracted and improved while the patient is in bed. Muscular and breathing exercises are necessary, especially in digestive disturbances. A patient should not be allowed to get up out of bed with his muscles flabby. We should pay particular attention to the patient's morale and give encouragement; also gauge the patient's powers by a study of the various organs and by blood pressure measurements, by metabolism, etc.

DR. JAMES W. SEVER, Boston: In regard to orthopedic surgery—the pathetic side of it is that most of the cases which require orthopedic treatment are cases we should never see, due to the fact that preliminary reconstruction surgery has not been properly carried out.

There are four or five general conditions which all of us dealing with the rehabilitation or reconstruction of a disabled person should know. Classified under five headings they are: 1. The physical condition, that is, we should know the physical condition of the individual and his capacity; 2. The mental condition, whether his mental attitude is right or not, and his capacity; 3. His economic standing and responsibility in the community; 4. His training, either his physical training or his training

in regard to the industry in which he is working, for the possibility of leading up to a suitable employment either in good health or debilitated health; 5. His debilitated state. Speaking of reconstruction, I didn't quite understand Mr. Parks. He said that when they left the hands of the doctors they needed a helping hand. Just what he meant, I don't know. I believe in two things, the ideal and the practical—the possible. I think we should give adequate treatment in the hospitals and after they leave the hospitals. Patients are put into the hospitals with the idea of getting them out. They should be followed up from start to finish as are private patients. It would be a tremendous expense. The insurance companies have no follow-up: they are afraid to get into it because of the expense it would involve. The term "replacement" in industry I think is better than "rehabilitation."

Speaking of the "back to the farm" movement, I have a patient, a boy with infantile paralysis, who works on a farm and runs a tractor. I think a lot of this replacement comes down to the old sergeant's point of view, which is just "plain guts."

DR. ROBERT J. GRAVES, Concord, N. H.: Reconstruction on the Boston & Maine was about to be born when the strike hit us and had to lie dormant. We find it hard to concentrate patients in one place, to take them a distance from their homes. We are forced to get along with the best aides we might have. One of our principal difficulties arises with cases in Boston. A man is more fortunate if he doesn't get injured in Boston for he will have more individual attention and care. We don't have the difficulty of replacing men because we have a good many types of job. Our difficulty lies in what the unions will let us do. We are finding that the time of disability is very much shortened over what it was when the old system was in vogue before the strikes. The new men do not lay off as long as the older men did for similar injuries.

DR. A. H. PIERCE, Boston: Dr. Anthony spoke about politics. Politics doesn't enter into the Veterans' Bureau at West Roxbury. At West Roxbury we have nervous and mental cases, and our problem is sometimes one of custodial care. A patient is given a thorough overhauling, a thorough history is taken, and a thorough mental examination is made and a thorough social service history is obtained. With those things the day's routine is planned. It comprises a whole day of occupation, half of which is occupational therapy, so-called, and the other half is exercise and amusements which run into the evening. The occupational therapy consists of the ordinary run of basketry, toy making and weaving and some painting. It is

done partly in the crafts shop and partly in the wards. In addition they have vocational training which consists of education. The whole scheme is therapeutics, but in so far as it may enter into vocation later, it is planned so that the subjects of the grammar and high schools are taught. Draughtsmanship is taught and agriculture and various other subjects. We have eight or ten acres, and I am trying to get a green-house. In addition we have an up-to-date equipment for physiotherapy. Then there is the personal touch of the ward surgeon with the patient. It is fundamentally psychoanalysis, although I don't like to use that term.

DR. JOHN BRYANT, Boston: I have tried to find out how this convalescence program can be worked out better in civil life. The time factor is important, whether we are working on the patient on a ten-day basis, or whether the changes involve weeks or months of treatment. The only solution is a series of convalescent hospitals where all these different factors can be run together simultaneously with a director of the group who is familiar with all the possibilities of the various parts of the group.

About occupational therapy, the emphasis has been put upon arts and crafts. Arts and crafts is only the elementary phase of the occupational therapy work, and if one stops at that, one does not use all the efforts. If a patient gets through the acute stage, the arts and crafts stage is desirable for the first process of interesting the patient in his surroundings again; but that must be succeeded by a stage in which there must be something more serious to be considered by the patient who must do some work in the world. The highest phase of occupational therapy must be connected with the patient's mental aspect and the job he is going to do when he is discharged, and the biggest thing an occupational aide can do is to give the patient something which will make him better able to earn a living and make him feel that his hospital experience was not a waste of time. I saw in the Army a great many men who were raised from the labor status to an artisan status. The work which I found most valuable and most easily adaptable is apparently paid little attention to, and that is straight academic work; and it was extraordinary to find how glad these fellows were to choose academic work. At Upton the cases were cases of osteomyelitis. I suggested that the work be directed to the patients who couldn't get out of bed, and suggested that the aides should offer to the patients the choice between arts and crafts and academic work. They all chose some book work, some study that would do them good. There were over 400 men working their heads

off trying to learn something that would enable them to earn money when they got out.

Previous to the meeting of the Suffolk District Medical Society, the Medical Advisory Committee, appointed to assist the Industrial Accident Board in dealing with purely medical questions, met at the State House for the purpose of conferring with physicians who might want to bring up matters affecting the work done by physicians under the laws governing professional service rendered to injured employees. Also a number of representatives of insurance companies were present by invitation.

Dr. F. J. Cotton, chairman, called the meeting to order and explained the status of this committee, which is that of an unofficial body serving without pay, designed to represent the profession and assist the Industrial Accident Board. The members of this committee were recommended by the medical societies. Dr. Cotton spoke of the general effect of the application of laws, in rehabilitation of injured workmen, and felt that progress is being made and asked the physicians present to submit any evidence of unsatisfactory administration of the Industrial Accident Act, or to ask questions about any doubtful points.

Dr. Jakmann of South Boston reported that whereas he formerly was called upon to treat many injured workmen, that now he sees very few and felt that patients were being diverted away from their usual medical attendants and sent to physicians in the employ of the corporations or the insurance companies. Dr. Gunning of Fall River felt that physicians should receive more consideration and that there is a somewhat general feeling of disappointment among the physicians of that city because of the employment of nurses to the exclusion of physicians, and also that the selection of physicians had not always been judicious. He criticised the custom of sending nurses to the families of the employees and felt quite sure that doctors were being deprived of legitimate opportunities and further that when doctors are employed that the fees were inadequate and hence a corresponding quality of service was given. One specific criticism of the work done by doctors was that there was a common distribution of aspirin for most troubles and if relief did not follow the aspirin treatment it was supplemented by a dose of salts. These conditions constituted a problem for the medical profession rather than for the Legislature. He affirmed that the insurance companies are destroying medical practice by the employment of unqualified men and paying low fees.

A member of the committee asked for specific evidence that nurses are practising medicine in Fall River, and Dr. Gunning answered that they practically do and that there is evidence in support of this claim. He reported a specific instance of abuse on the part of a mill official

who, on finding that an operative had been to a physician not approved by the management, said that if the operative persisted in this course that he would be discharged. Mr. Holland of Malden reported that nurses are doing the work that should be done by doctors and he felt that the work should not all be done by the selected doctors and that the profession should use its influence in protecting the unselected practitioner.

Dr. Croft of Greenfield reported that workmen were given cards with the names of selected doctors printed thereon, and after the district society had taken the matter up and published information, setting forth the freedom of choice provided for the employee under the law, there was some improvement, but that there is yet much to be done, for financial conditions have changed and that personal freedom should be guaranteed.

Dr. Cross of South Boston felt that the insurance companies do business on wholesale plan and that this condition is responsible for poor work. If a patient reports that he is under the care of a doctor of his own choice that doctor is displaced. He affirmed that in one place a nurse with six months' training was attending cases and is now teaching another nurse to do this class of work.

Dr. Donald Baker of Boston spoke of the methods in vogue in his clinic in dealing with accident cases and asserted that he had no desire to pre-empt the field or to coerce the patient. He felt that among other things the fact that employers often did not provide work for the employee when ready to return to his job is a matter that should be adjusted. So far as he is concerned every effort is being made to keep the patient and his family doctor in their accustomed relation.

Dr. Gunning felt that there could be no objection to the employment of those physicians who did good work, but Dr. Duff of Charlestown endorsed the statement of a previous speaker relating to the directions on the circular given to employees, directing the employment of selected doctors. A physician employed in a candy factory said that she had two good nurses working under her direction and that the nurses desire to know just what the doctors want the nurses to do, because the nurses feel concerned lest they may unwittingly antagonize the doctors.

Mr. Marston, a representative of the American Mutual Insurance Company, claimed that the company is bound under the law to furnish medical care and it is up to the employee to accept.

Dr. Charles L. Seudder, in responding to Dr. Cotton's invitation to speak, said that there is a definite feeling that the relations of the injured employee, the insurance companies and the employers are in an unsettled state. He felt that this class of injuries calls for well-

trained men and that the insurance companies are acting as business organizations from a business point of view and therefore are desirous of reducing the period of disability to the shortest possible time. He explained that the slightly different methods of well-trained surgeons would result in practically the same good results. In analyzing the results of treatment the insurance companies ask why in the same type of accidents one man recovers sooner than another, and why one man is out of work longer than another. These companies are looking for standardized treatment and they would probably find that it is less expensive in the long run to pay for adequate treatment.

Dr. Arthur Broughton reviewed some of the activities of the committee of which he was chairman and explained the difficulties encountered. He had tried to have the laws relating to accident insurance clarified in relation to disease modified by or coincident to accidents, the elucidation of the word "unusual" and revision of that part of the law relating to full treatment.

When these recommendations for improvement were presented to the legislative committee, although there was no apparent opposition, the committee report was "leave to withdraw." He explained that he had asked to have his committee dissolved because the work done was a waste of time. He felt that the medical societies have concluded that the attitude of the Industrial Accident Board has been reasonable. So long as such terms as "unusual" are allowed to remain in the law, there will be more or less trouble.

Mr. Linscott, a representative of the Employers Liability Company, said that the interests of the company and the patient are identical. Both want early recovery. The unfortunate position of the company consists in the "post mortem" analysis of the work done by doctors. Some doctors get the patients back into industry promptly and others get poor results, and it is a mistaken idea that the companies want the cheapest service, for poor service means extra compensation. The companies have created clinics only in the larger communities and these take the place of out-patient departments of hospitals, but no patients are forced to go to the company clinics, but the patients soon learn of the advantages of the clinics because of the better equipment than can usually be found in doctors' offices. All that is wanted by the companies is good service and the employed doctors are capable, and any capable doctor is acceptable in places where there are no clinics. It is a common custom to put the name of every doctor in a town on the card of instruction. The greatest trouble results from disinclination to accept the decree of the medical advisory committee and every means is taken to bring pressure to bear on the insurance company. Usually the relations of the doctor and

the insurance company are pleasant and the companies use every effort to dissuade patients from bringing suits against doctors. So far as his company is concerned, he felt that an amendment to the law which would provide for full attendance is desirable and further provision for authority authorizing the employment of competent physicians, for some ignorant workmen cannot exercise good judgment in the selection of a doctor. The companies want to have the patients in the hands of good doctors.

Dr. Ewing of Stoughton felt that it is an endless task to explain the features of the compensation law to patients and felt that it would be of great interest to know how much other people received through the operation of the law as compared with the money paid to doctors. He submitted the following statement:

According to the latest Annual Report of the Department of Industrial Accidents for the year ending June 30, 1921.

There are 36 insurance companies authorized to do business in Massachusetts under the Workmen's Compensation Act.

It appears that this form of insurance covers about 50,000 employers and 1,000,000 employees.

It also appears that among these employees there were 48,315 tabulatable injuries.

It also appears that there was paid in this one-year period, \$5,666,859.93: of this, \$1,639,670.49 for medical and hospital services; \$639,608.26 for fatal cases; \$3,387,581.18 for non-fatal cases.

My request is that the report should continue to show, if possible:

1. The total amount paid by the 50,000 employers.

2. The total amount paid the insurance agents, representing the 36 companies, for the service which they perform of selling compensation insurance to employers who are practically obliged, by the law of the State, to buy this insurance.

3. What portion of the total amount received from employers is returned in taxes to the State and Federal Government?

4. What remains in the hands of the insurance company?

5. Also, if it were possible, what it costs the insurance company to transact the business aside from the above items, leaving

6. The final profit which accrues to the 36 insurance companies.

All or any part of the above information would be of interest and eminently fair. The publication of merely a portion of the facts in the annual report leaves one, who desires only the truth, unsatisfied.

EDWARD H. EWING.

Stoughton, Mass.

Mr. Holland of Somerville felt that the general practitioner should give this work over to the clinics.

Dr. Gunning objected to some statements made by Dr. Seudder and the representatives of the insurance companies, for he felt that good judgment had not been exercised in the selection of the doctors in Fall River.

Dr. Broughton regretted that Mr. Linscott, of the insurance company, had left the meeting, for he did not feel at liberty to make certain statements in his absence, but hoped that Mr. Linscott would elaborate his plans at some future time.

Mr. Marston again spoke and expressed the opinion that physicians and the insurance companies are getting together and greater progress will be made if we work together. We must bear in mind that the law has been in existence only ten years and much had to be learned by experience, and experience is expensive. The former plan of getting medical service as cheaply as possible has been discarded. The good features of the law should be recognized, for now every mill employing 100 or more has to have a first-aid room, and whereas the legal profession has lost much the medical profession has gained a great deal in the aggregate.

Dr. Cotton explained that the trouble with the insurance companies had been ignorance and the trouble with the doctors had been inefficiency and the general practitioner cannot keep this class of work if unable to deliver the goods. The clinic will survive if it is efficient. The doctors must realize that insurance companies know a lot about doctors. A great deal has been accomplished and it must be recognized that this kind of work will go into the hands of those competent to deal with it and the mill carrying the financial burden will try to secure the best possible medical service.

Dr. Francis Donoghue asked for comments on the work done by the impartial doctors and explained the method employed in selecting them, which was very much like the plan suggested by a previous speaker.

Dr. Gunning thought that the impartial doctor should be appointed by the Governor, just as medical examiners are appointed.

Dr. Anthony of Haverhill spoke of cutting off compensation before the injured workman was fit to return to industry. This was explained as an infrequent occurrence in the ordinary machinery of business.

Dr. Jakmauh suggested more frequent consultations of the insurance companies with physicians and expressed the hope that publicity would be given to the whole subject through the columns of the BOSTON MEDICAL AND SURGICAL JOURNAL.

Dr. Cotton submitted the following statement:

It is my purpose, unless someone of the Accident Board objects, to bring forward the sug-

gestion which follows, for comment and discussion (but not for action), at the meeting November 22d.

That in all cases still under compensation after three months, brief reports be required to be sent in by the insurer or carrier to the Board; that in case any such reports seem to call for it, an examination and report shall be made by one of the Board's impartial physicians; this in order that

1. Conditions in the given case be definitely established early.

2. There may be a common understanding and agreement as to these conditions on the part of all concerned.

3. The Board may have records, at least of the more serious cases—as they should, beyond question.

4. The impartial physician, if called on, may do his part (acting as consultant as well as reporter) at a time when his work may help toward real results and recovery, instead of having him come in, very often uselessly, after many months, to take part in a case that has become merely a dispute.

This suggestion is offered with the purpose of helping all parties who are working together for more effective administration of the Act and it is hoped that some measure like this may bring about even closer co-operation between the interested parties.

The reasons for bringing forward this suggestion are, in the first place, that impartial examinations are unsatisfactory because necessarily one-sided; that they are professionally unsatisfactory in that the impartial, given no data, cannot do himself justice; in that they are, in the rule, so late as to be of no value, or little value, in the way of helping treatment.

Moreover, there is not a little dissatisfaction in various quarters, for various reasons, with the present arrangement.

Moreover, many patients are incapacitated longer than need be, because early treatment is not instituted.

Not often is this a result of reluctance of insurance companies to do the work. Much often-er cases are lost sight of because no adequate report is at hand or because it is not possible for the insurance company's examiner to reach the case; there would be no obstacle in the way of the Board's examiner.

It is thought that a good many hearings could be avoided under a plan like this, leaving more to be settled by simple conferences without medical dispute; unavoidable medical disagreement might under this plan be reduced to clean-cut issues and submitted after a Board hearing to a medical arbiter on medical issues only, an impartial agreed to by the Board, insurer, and the injured employee.

Subsequent to the open meeting the Advisory Committee met and endorsed the recommendations submitted by Dr. Cotton.

LEADERS ENDORSE CHRISTMAS SEAL SALE.

The Health Christmas Seal Sale of 1922 has been initiated with the encouraging approval of men well known to citizens of Massachusetts, including Major General Clarence R. Edwards; Eugene R. Kelley, M.D., State Commissioner of Public Health; His Eminence, Cardinal O'Connell; and His Honor James M. Curley, Mayor of the City of Boston.

WHAT THE HEALTH CHRISTMAS SEAL DOES IN MASSACHUSETTS.

Helps to support the National and State tuberculosis associations.

Supports the work of thirty county and city tuberculosis and public health associations affiliated with the Massachusetts Tuberculosis League.

Is helping to operate examination clinics in ten of the fourteen counties of the State, and a successful Seal Sale this year will make it possible to place examination clinics within the reach of every town in the State.

Supports twelve full-time expert field tuberculosis nurses and partly supports forty-three other public health nurses.

Supports seven summer health camps and two preventoria for delicate children and gives scores of other delicate children outings in the country.

Has helped to establish four open-air schools during the past three years.

Has helped to establish nutrition work in 100 cities and towns of the State.

Has promoted the Modern Health Crusade, which has enrolled over 300,000 school children in the formation of good health habits.

Has helped to establish dental clinics in fifty-three cities and towns of the State.

Finances the distribution of educational literature, posters, and pamphlets, and helps to conduct "Health Days" and "Health Weeks."

Maintains motion picture and marionette service and a Health Clown for promoting health education.

Publishes the *Health Journal* and promotes health education and interest in public health work through the press of the State.

Coöperates with other agencies in securing good health legislation.

Provides a clearing house for information regarding the organized fight against tuberculosis.

Provides material relief where that is necessary. The little Health Christmas Seal did it.

THE BOSTON Medical and Surgical Journal

Established in 1828

Published by The Massachusetts Medical Society under the jurisdiction of the following named committee:

For three years WILLIAM H. ROBEY, JR., M.D.
ROGER I. LEE, M.D.
ROBERT B. OSGOOD, M.D.
For two years JAMES S. STONE, M.D.
HORACE D. ARNOLD, M.D.
CHANNING FROTHINGHAM, M.D.
For one year HOMER GAGE, M.D., Chairman.
EDWARD C. STREETER, M.D.
EDWARD W. TAYLOR, M.D.

EDITORIAL STAFF.

DAVID L. EDSALL, M.D.
WALTER B. CANNON, M.D.
REID HUNT, M.D.
ROBERT W. LOVETT, M.D.
FRANCIS W. PEARSON, M.D.
JOHN P. SUTHERLAND, M.D.
S. BERT WOLSACH, M.D.
GEORGE R. MINOT, M.D.
FRANK H. LARNEY, M.D.

WALTER P. BOWERS, M.D., Managing Editor.
GEORGE G. SMITH, M.D., Assistant Editor.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid for the United States, \$7.50 per year for all foreign countries belonging to the Postal Union.

Material for early publication should be received not later than noon on Saturday. Orders for reprints must be sent to the printer with galley proof of paper. Upon written request, authors will be furnished free one hundred eight-page reprints, without covers, or the equivalent in pages in articles of greater length.

The Journal does not hold itself responsible for statements made by any contributor.

Communications should be addressed to The Boston Medical and Surgical Journal, 126 Massachusetts Ave., Boston, Mass.

THE PROBLEMS OF PSYCHIATRY.

THE attention of our readers is called to the article by Dr. Bronson Crothers in this issue, because it deals with a subject which should interest every general practitioner.

The problems discussed have been considered in several medical society meetings during recent years, but have not seemed to arouse great interest among physicians in general practice. The contention has been made more than once that the vagaries of childhood should be dealt with early in order to prevent morbid mental deviations, and since the regular family attendant is usually the first to observe such deviations, he should realize the importance of early treatment which should, in some cases, be applied to other members of the family as well as the child. The doctor in charge may be quite able to regulate the composite behavior of the family and prevent disaster if he will carefully study all the conditions, or determine the necessity of seeking expert treatment for a case which may be cared for more advantageously by another.

Unfortunately clear evidence of the development of serious mental or moral deviations is often lacking or difficult of interpretation, and it is incumbent on the physician to study this phase of practice just as much as he would prepare himself to detect other dangerous conditions or tendencies.

As Dr. Crothers plainly shows, the statements made by many writers puts the profession on the defensive for, if the oft repeated assertion that a large proportion of our insane population could have been cured by early treatment is true, we owe it to the state, as well as the individual, to prevent many of the tragedies of life.

Although psychiatry may be an undeveloped science, enough has been said and written to put us on our guard and lead to more definite interest in the subject. The majority may not be very much concerned in the controversies of the pioneers except so far as different views are suggestive, but we should endeavor to separate the wheat from the chaff, for out of all the complexities there will come recognized rules of procedure, since the interest of keen minds is now concentrated on the problems involved. Extreme and unsound views will undoubtedly be discarded. Other difficult questions have been solved and we can confidently expect that sane and patient students will clarify the present confusion and establish methods of approach, technique of procedure and give advice which will enable family physicians to deal constructively with indications of psychic disturbances.

The state has taken one forward step in the enactment of a law which obligates the Board of Registration in Medicine to incorporate into examinations questions relating to psychiatry. This, in time, will bear fruit.

Practitioners already registered may devote time to these problems with profit to themselves and their patients.

THE VAGARIES OF INFANT FEEDING.

FEW phases of medicine have been in such a state of flux during the last twenty years as infant feeding. In Boston the percentages have been calculated to a nicety and the babies have done well. Elsewhere (and now in Boston) babies have been fed on whole milk dilutions based on their protein and calorie needs for body weight, and they have done well. Many types of sugars and starches have been used, and the milk protein has been modified by many methods. Buttermilk has been mixed with Karo corn syrup. Milk has been dried and re-dissolved. It has been peptonized. Protein milk has been used for certain disorders, with and without the addition of sugar.

One of the more recent developments has been that of the butter flour mixture, introduced in 1918 by Czerny and Kleinschmidt. The original formula consists of butter 7 grams, flour 7 grams, cane sugar 5 grams, and water up to 100 c.c., the butter being first cooked, then the flour added, and the two cooked together until brown. The resulting butter soup is mixed with boiled whole milk in varying proportions dependent on the weight of the infant to be fed.

Brown, Courtney, and MacLachlan, in the *American Journal of Diseases of Children*, November, 1922, describe their modification of this mixture, consisting of butter $7\frac{1}{4}$ teaspoons, cane sugar $5\frac{1}{4}$ teaspoons, flour $1\frac{1}{3}$ teaspoons, and water $17\frac{1}{2}$ ounces. This changed butter soup with its higher starch content is also added to whole milk. Excellent results have been obtained by many observers with some type of butter soup feeding, especially in the newborn and in cases of chronic malnutrition and difficult feeding with no particular symptomatology. Its use is advised against in acute conditions and in those where an intolerance to one or more food constituents is present.

The use of boiled butter instead of cream in modified milk formulae is advocated by Dr. Harry Lowenbuck, speaking before the Philadelphia Pediatric Society, *Archives of Pediatrics*, October, 1922. He finds that boiling sweet butter for two minutes reduces the fatty acid content by more than half, or to a much greater degree than occurs by boiling cream. Butter so boiled can be added to skimmed milk in considerably greater quantities than can cream, without causing digestive disturbances.

The conclusions that we are forced to reach are that infants thrive on fat, carbohydrate, protein, salts and water, and that the types and quantities of these principles can be varied considerably as to kind and quantity without untoward results, and often with probable benefit. The only warning we would issue is that experiments be kept within the bounds of safety and be not performed by those who are untrained in the art of infant feeding and incompetent to judge their results.

VOX CLAMANTIS.

The American Medical Press of New York, a recently founded publication, voices, in its issue for November, a protest against "The Closed Hospital Menace." It is directed against "the undemocratic institution which excludes all but a chosen few from within the sacred circle constituted by the staff."

The Medical Press, apparently, would have the doors of all hospitals flung open to all practitioners, who could send in their patients at will and treat them according to their own dictates. It has been our experience that physicians who merit confidence generally have no difficulty in being included in some "sacred circle." Possibly those who find themselves unable to gain admittance are not always deserving of the privilege.

In the same issue the Medical Press finds indications of "A startling alliance between the Rockefeller interests and the Hearst publications." This is based on a series of articles written by Paul H. De Kruif, B. S., Ph.D., of

the Rockefeller Institute, aimed at proprietary medicines and drugs. Dr. De Kruif is a pathologist and bacteriologist. It is our opinion that a doctor of philosophy is entitled to his title; the Medical Press apparently does not agree with us, since the title of Dr., wherever it occurs before Dr. De Kruif's name, appears in quotation marks.

According to the Medical Press, "The De Kruif propaganda marks another step in the plans of the Rockefeller interests and the American Medical Association to undermine public confidence in the family physician and bring about a popular demand for State medicine."

This is interesting, if true, but we find ourselves unable to become too greatly disturbed by the danger.

News Notes.

ROYAL SOCIETY OF MEDICINE.—In the "Proceedings of the Royal Society of Medicine," for November, 1922, published in London, the Sections of Dermatology, Epidemiology and State Medicine, and Medicine are reported. At the Section of Dermatology meeting, July 20, 1922, cases were shown by various dermatologists. The Section of Epidemiology and State Medicine met April 28, 1922, the paper abstracted being by Frederick Dittman, M.D. Glas., F. R. C. P. Edin., on Some Outbreaks of Enteric Fever due to Carriers of Infection. At the Section of Medicine, May 23, 1922, William Hunter, C. B., M. D., F. R. C. P., read a paper on The Nervous and Mental Disorders of Severe Anaemias in Relation to Their Infective Lesions and Blood Changes.

DEATH RATE IN BOSTON.—During the week ending Dec. 2, 1922, the number of deaths reported was 235, against 196 last year, with a rate of 16.04. There were 34 deaths under one year of age against 28 last year. The number of cases of principal reportable diseases were: Diphtheria, 60; Scarlet Fever, 29; Measles, 53; Whooping Cough, 50; Typhoid Fever, 3; Tuberculosis, 44. Included in the above were the following cases of non-residents: Diphtheria, 10; Scarlet Fever, 4; Measles, 2; Typhoid Fever, 1; Tuberculosis, 24. Total deaths from these diseases were: Diphtheria, 6; Measles, 3; Typhoid Fever 1; Tuberculosis, 7. Included in the above, were the following cases of non-residents: Diphtheria, 3.

BOSTON CITY HOSPITAL.—At a recent meeting of the Surgical Staff of the Boston City Hospital, it was voted to resume operating in the Surgical Amphitheatre on Saturday mornings at ten o'clock.

THE AMESBURY HOSPITAL.—That Amesbury will have a new hospital in the not very dis-

tant future, seems now an assured fact. A most favorable site has been secured, and the architect will soon submit the plans to the officers of the Amesbury Hospital Association, and also to the local doctors who will constitute the medical staff of the institution. The new hospital is to be erected, equipped and maintained on the community plan. As proposed, it will consist of thirty rooms, including a maternity ward, accident ward, and two large wards—one for men and one for women—operating rooms, and the remainder for private rooms. The officers of the Association are: *President*, C. I. Pettingell, Esq.; *Secretary*, E. J. Graves; *Treasurer*, H. B. Locke.

J. F. R. BIRON, M.D.

THE LAWRENCE MEDICAL CLUB.—The Monthly Meeting of the Club was held Nov. 27th, 1922, with Dr. T. W. Murphy, at the Red Tavern. Chairman for the evening was Dr. H. H. Nevers; subject: "The Work of Dr. Carrel at the Rockefeller Institute." Miss Charlotte Mikalson.

F. H. JENSON, a chiropodist whose advertisement might be construed as indicating that he is a surgeon, was recently brought before the court on complaint of an officer of the Department of Public Safety. He pleaded *nolo contendere* and the judge placed his case on file with the condition that he should use the term surgeon as a compound word, surgeon-chiropodist. Action against Mr. Jenson was inaugurated by the State Association of Chiropodists for the purpose of compelling practitioners in this field to avoid any form of advertising that might deceive the public.

THE MASSACHUSETTS SOCIETY OF EXAMINING PHYSICIANS.

The November Meeting of the Massachusetts Society of Examining Physicians was held Nov. 27, 1922, following a dinner at the Copley-Plaza Hotel, 35 members being present. The President, Dr. William P. Cones, presided. The general subject of the meeting was "The Human Back," discussed from various angles.

Dr. James W. Sever was the first speaker and he said that the diagnosis of a lame back without demonstrable x-ray findings had to be based purely on subjective symptoms, therefore it was a difficult proposition to determine the amount of the disability. He laid great stress on the importance of having an *immediate x-ray* on every case of injured back, if only as a record, for they often show bony changes which might later be attributed to the accident. He also emphasized the importance of having all cases of back injuries under *proper treatment* and he spoke of the fact that a survey of the cases of

back injury which come to the attention of the Massachusetts Industrial Accident Board show that with or without treatment, their time for recovery was six months, and that many of them existed for a very much longer time. Dr. Sever accompanied his talk with a number of x-rays shown on the screen, which demonstrated the arthritic changes which may occur in the spine without symptoms and which may cause symptoms after a slight injury. He also showed various cases of fracture of the spine from patients who have recovered after proper treatment.

The second speaker was Dr. Lloyd T. Brown, and his point of view was one largely of posture. He demonstrated by pictures and x-rays 3 distinct types of backs: the flat, broad back; the narrow lithe type and the type which fell in between. It was an interesting fact that the x-ray evidence showed that the very vertebrae were in accord with the type of back as seen in the individual, and from an examination of the x-ray of the back, you could tell to which type its owner belonged. He emphasized strongly the necessity of teaching individuals to stand correctly and the importance of beginning these exercises in childhood. He said that he felt the time would come when individuals in industry would not be allowed to do work for which they were structurally unfit and this sorting process would be carried out scientifically by doctors properly trained.

The discussion of these two papers was opened by Dr. A. W. George, who said there have been and are more loose diagnoses made referable to the vertebrae than any or all parts of the body put together. The medical man and roentgenologist should study the normal, study age and its consequent changes in the vertebrae, study occupation and, last but not least, the mechanics of injury and the conditions that can and can only refer to injury in the vertebrae. He also said that given a workman beyond 40 years of age who has done laborious work throughout the period of his working days, you will find the individual changes entirely different from that found in young workmen. It is rare to find such an individual who does not show some degree of postural changes, scoliosis and subsequent wedging and deformity of the vertebrae, also hypertrophic changes. These latter changes he considers just as much a part of the workman's age as his hair growing gray. As to sacro-iliac dislocation, he said here we have the most frequent back lesion diagnosed today, or in the past, and yet we have rarely any tangible evidence of it from an x-ray point of view.

Dr. Francis D. Donoghue then carried on the discussion and said that the x-ray could never be a substitute for a real medical diagnosis. He felt that there was no definite time for an individual with a lame back to get well.

that time of year, age of the individual and the type of work he had been doing must be considered. He said that the orthopedic specialist was too apt to speak in terms of "plaster and eternity instead of braces and work." Dr. Donoghue also said that he considered all men on the level, that they did not loaf unless they had a real injury and that malingering, therefore, was confined to those unable to earn and the diagnosis belongs to those who are "diagnostically destitute."

The last to participate in the discussion was Dr. Frank Schubmehl, of Lynn, who gave some actual experiences in trying to fit men to their positions according to their physical development, and spoke of the difficulties of so doing, particularly in the present industrial situation.

HILBERT F. DAY, M.D.

A MERITED HONOR.

A well deserved tribute has been paid to a former Boston physician. The Radiological Society of North America has conferred a gold medal upon Dr. Percy Brown for the pioneer work which he has done in his chosen field. A graduate of the Harvard Medical School in 1900, he turned to x-ray work immediately after completing his internship at The Boston Children's Hospital. The field was new. The difficulties were great. The dangers involved were unknown. Those who work in the well-equipped x-ray laboratories of the present day cannot realize what it meant to work in a small basement room on Massachusetts Avenue near the old Children's Hospital on Huntington Avenue, which was torn down many years ago. Yet patients had to be sent out in this way to the laboratory started by Codman and continued by Brown because no suitable current could be secured in any other way. Dr. Brown also was instrumental in the establishment of x-ray departments at the Carney and St. Elizabeth's Hospitals. To him and to the lamented Walter Dodd fell the work of instruction in Roentgenology in the Harvard Medical School. They, together with Dr. Williams at the Boston City Hospital, had to be pioneers in the interpretation of plates and in the use of the fluoroscope. Dr. Brown, in spite of the effects upon his health resulting from the work he had done, had no more hesitation than did Dr. Dodd in giving his best first to the British and then to the American forces in the Great War. Fortunately, Dr. Brown did not have to make the supreme sacrifice made so bravely by Dr. Dodd.

Although Dr. Brown is now associated with the Jackson Clinic in Madison, Wisconsin, Boston still claims him. His friends here and everywhere rejoice in the great honor conferred upon him and wish him many years more of useful service.

DR. MAC KERROW'S SENTENCE.

THE *Worcester Telegram* reports that Chief Justice Walter Perley Hall of the Superior Criminal Court, on Nov. 27, 1922, sentenced Dr. Horace G. MacKerrow to serve not less than four years and not more than five years in the State's Prison at Charlestown, the first day to be in solitary confinement. The crime for which Dr. MacKerrow stands convicted was an assault on a Chinese woman in his office. Up to the time of the complaint Dr. MacKerrow had conducted a successful practice in Worcester for the past seventeen years and was prominent in church and fraternal organizations. His counsel stated that he had signed petitions from at least one thousand prominent Worcester citizens asking for clemency. Although the doctor denied the charge, an alleged confession made to the detective was in evidence. This was explained by the doctor as being the result of confusion at the time.

Obituaries.

JOSEPH GURNEY PINKHAM, M.D.

Dr. Joseph G. Pinkham, for forty years a medical examiner in Essex County, vice-president of the Massachusetts Medical Society in 1909-10, and acting president in the absence abroad of the president, has died at his home in Lynn, at the age of eighty-three, the end coming after an illness of several months, on November 30, 1922.

Born in West Gardiner, Me., Oct. 20, 1839, the son of Elias and Fannie (Sampson) Pinkham, he attended school there and then entered Haverford College in Pennsylvania, where he received the degree of A.B. in 1863 and A.M. in 1866. The degree of M.D. was conferred on him by the Long Island College Hospital in 1866, and in 1868 he came to Lynn, opening an office on Silsbee Street, opposite the site of the present Friends' Church.

For thirty years he was chief surgeon at the Lynn Hospital, was a Fellow of the American College of Surgeons, a consulting surgeon at the State Hospital for Insane at Hathorne, a trustee of the State Hospital at Foxboro, president of the Massachusetts Medico-Legal Society, and president of the Commonwealth Savings Bank. For twelve years he was a member of the Lynn School Board, four years serving as chairman.

He is survived by three daughters and two sons. Dr. Pinkham's wife, who was Georgianna MacKenney, of Maine, died five years ago.

MARSHALL CALKINS, M.D.

Dr. Marshall Calkins, a retired Fellow of the Massachusetts Medical Society, died of old age at his home in Springfield, November 26, 1922, at the great age of ninety-four years. Born September 2, 1828, at Wilbraham, Mass., he attended Wesleyan University at Middletown, Conn., and Union College at Schenectady, N. Y., receiving from the latter the degree of A.B. in 1853 and A.M. in 1856. He studied medicine with Calvin Newton of Worcester and took an M.D. at the Worcester Medical College in 1848 but, not satisfied with this, the college becoming extinct in 1859, he entered Dartmouth Medical School and graduated in medicine twenty years later, in the class of 1868. He settled in practice in Springfield, having joined the State Medical Society in 1862. He was retired in 1893. From 1873 to 1879 Dr. Calkins was professor of physiological and microscopical anatomy in the medical department of the University of Vermont. He was attending physician to the Springfield City Hospital in its early days and later consulting physician to the Springfield Homes for Friendless Women and Children; a member of the board of examining surgeons for pensions. Until recently he was engaged in general practice. Among his memberships were the American Medical Association, Hampden Medical Club, corresponding member Boston Gynecological Society, member Vermont State Medical Society, and American Association for the Advancement of Science.

Dr. Calkins was married in 1855 to Miss Adelaide A. Hosmer, daughter of Gen. E. M. Hosmer of West Springfield. She was a member of the school committee for twelve years and died in 1909. He is survived by his son, Dr. Cheney H. Calkins of Springfield, a Fellow of the Massachusetts Medical Society.

RECENT DEATHS.

DR. HENRY M. SMITH died at his home in Lee at the advanced age of 73 after an illness of several months. He had served as medical examiner and town physician and had held several town offices.

DR. CHARLES WILLIAM GALLOUBE, a Fellow of the Massachusetts Medical Society from 1883 until 1921, when he resigned, died in Boston, November 29, 1922, at the age of sixty-four. He was born in Lynn, May 12, 1858, the son of Dr. Isaac Francis Galloube, a prominent physician of that city. Charles graduated at Harvard in 1879 and from Harvard Medical School in 1883, serving as surgical house officer at the Massachusetts General Hospital. He had an office on Commonwealth Avenue, Boston, for many years.

DR. WALTER EVERETT WHITNEY, a specialist in ophthalmology, otology, laryngology and rhinology, died at the Eastern Maine General Hospital at Bangor, Maine, November 28, 1922 at the age of fifty-seven. He was a graduate of Jefferson Medical College, Philadelphia, in 1893 and had practised in

Richmond and Oakland, Maine, before settling in Bangor in 1909.

DR. CHARLES ADELBERT LIBBY, a graduate of the New York Homeopathic Medical College and Flower Hospital in 1873, died in Arlington, his home and place of practice since graduation, November 28, 1922, aged seventy-one. He was a native of Limington, Maine and a member of Hiram Lodge, A.F. & A.M., Menotomy Royal Arch Chapter and of Boston Commandery of Knights Templar. He is survived by his widow, who was Miss Mahel Small.

DR. FREDERICK ARTEMAS SIMONDS, a Fellow of the Massachusetts Medical Society, died at his home in Wakefield, of heart disease, at the age of thirty-four. He had been ill for several weeks, the end coming on December 2, 1922.

He was a graduate of the Wakefield High School in 1907, of Tufts College Medical School in 1914, serving as house officer at the Boston City Hospital and practising in Cambridge until becoming a member of the Harvard Unit for service abroad with the British army during the World War. He gave a good account of himself while in the army, was in the aviation corps at one time, and on returning was a member of the Medical Corps of the 101st Infantry. He settled in practice in Wakefield.

Dr. Simonds was a member of the American Legion and a Mason.

The Massachusetts Medical Society.

MEMBERSHIP CHANGES FOR THE MONTH OF NOVEMBER, 1922.

OFFICIAL LIST (10th)

Compiled by the Secretary.

ALPHABETICAL LIST.

The names of the new Fellows, following the examinations of November 2, will be found in the *Directory* of January 1, 1923.

Adams, Letitia D. Jamaica Plain, office Boston, 82 Commonwealth Ave. (from Suffolk to Norfolk).

Adams, Walter H., from Northampton to Florence, office Northampton, 34 Bridge St.

Ahlstrom, Hjalmar, Quincy, now 96 Garfield St.

Andrews, Robert E., from Ludlow to Springfield, office Ludlow, Ludlow Mfg. Associates.

Anger, Louis L., from Worcester to Montreal, Can., 329 Stuart Ave.

Brown, William James, from Cambridge (Middlesex South) to Boston (Suffolk), 316 Huntington Ave.

Cabot, Richard C., from Boston (Suffolk) to Cambridge (Middlesex South), Emerson Hall, Harvard University.

*Calkins, Marshall, died at Springfield, Nov. 26, 1922, aged 94.

Carr, Earl B., from Montrose, Minn., to Silver Creek, N. Y., 37 Oak St.

Chambers, Ralph M., from Westborough to Medford, office Boston, Room 109, State House.

Cobb, Gardner N., Worcester, from 24 Elm St., to 21 High St.

Collins, William J., Northampton, from 150 Main St., to 136 Main St.

Copeland, Elmer H., Northampton, from 168 Elm St., to 250 Elm St.

Cutler, George David, office now Boston, 270 Commonwealth Ave.

Davenport, Bennett F., Watertown, 11 Summit Rd.

Doie, George William, died at Lawrence, Nov. 21, 1922, aged 71.

Faxon, Nathaniel W., from Boston (Suffolk) to Rochester, N. Y., 6 Portsmouth Terrace (non-resident list).

1899 *Gallagher, William Howard*, Boston, 91A Court 1922 Street. Restored by Council, Oct. 4, 1922.

Gilman, Florence, Northampton, now 20 Elm St., Smith College.

Gordon, Samuel F., Philadelphia, Pa., now 206 E. Roosevelt Blvd.

†*Grainger, William H.*, from East Boston to Winthrop, 49 Bartlett Road.

Harrington, Elmer J., Holyoke, now 239 Maple St.

Hill, T. Chittenden, Boston, from 31 Bay State Rd. to 270 Commonwealth Ave.

Hubbard, Eliot, Jr., Roxbury, office now Boston, 520 Commonwealth Ave.

Hutton, Willis A., from Shelburne Falls (Franklin) to Swampscott (Essex South), 76 Farragut Rd.

Kaplovitch, Henry, Haverhill. Name changed to Kapp. Henry, 50 Merrimack St.

Koppel, William, from Boston to Chelsea, 199 Chestnut St.

Little, Abby Noyes, Diarbekir, Turkey in Asia. Near East relief.

Lowry, Franklin P., Newton, now 457 Center St.

Metcalf, Ben H., from Denver, Colo., to Phoenix, Arizona, 391 North 4th Ave.

Miller, Charles Herman, died at Dorchester, November 23, 1922, aged 59.

Morrison, Laurie B., from Boston (Suffolk) to Brookline (Norfolk), office Boston, 370 Marlborough St.

Murray, Halstead G., Framingham, now 45 Newton Place.

O'Connor, Alfred S., Worcester, from 22 Ledge St. to 314 Grafton St.

Perry, Herbert B., from Northampton to Pelham, office Northampton, 55 New South St.

Pinkham, Joseph Gurney, died at Lynn, November 30, 1922, aged 83.

Pratt, John Washburn, died at Dedham, November 17, 1922, aged 68.

Ripley, Horace G., from Roxbury (Norfolk) to Brattleboro, Vt., Brattleboro Retreat (non-resident list).

Lowland, William D., from Lynn (Essex South) to Newton (Middlesex South), office Boston, 220 Clarendon St.

Sager, Ernest T., office now Boston, 270 Commonwealth Ave.

Safford, Wilbur Pray, died at Brockton, November 16, 1922, aged 67.

Sawyer, Edward J., Newton, office Boston, 520 Commonwealth Ave.

Smith, George Gilbert, Boston, from No. 352 to No. 7 Marlborough St.

1917 *Smith, Lillian Richardson*, Lawrence, 92 Bailey 1922 St. Readmitted by Censors, Nov. 2, 1922.

Sullivan, Russell F., from New York City to Boston, 240 Newbury St.

Symonds, Alice G., now Churchill, Alice Symonds, Darlings Lake, Yarmouth Co., Nova Scotia.

1892 *Tower, Frederick Russell*, Boston, 51 Hunting 1922 ton Ave. Restored by Council, Oct. 4, 1922.

Whiteside, George S., from Portland, Oregon, to New Haven, Conn.

Williams, Harold, Boston, from 528 to 535 Beacon St.

Zabriskie, Frank Hunter, died at Greenfield, October 25, 1922, aged 63.

ADDRESSES UNKNOWN.

Bolton, Charles James.
Brown, Fairy Potter Palmer.
Fleury, Oswald Theodore.
Kassees, Sand H. A.
McIntock, Elsie.
MacKnight, William Frank.
Potter, John Claude.

Rabe, Edith Ruth Meek.
Sziklas, Charles.
Wetherbee, Roswell.
Williamson, Cordelia Isabella.

Changes of address should be sent to the Secretary, whose address will be 182 Walnut Street, Brookline 6, Mass., after December 20.

Correspondence.

THE MORTALITY OF DIABETES.

November 27, 1922.

Mr. Editor:

Referring to Hoffman's statistics of the mortality of diabetes, in your issue of July 27, a word of caution as to inferences of incidence ought to be spoken. For instance, the highest mortality per 100,000 is 38.4 for Malta; while the lowest is 1 for Venezuela. Now this does not mean that diabetes is 38.4 times as frequent in Malta as in Venezuela. It would very likely be nearer the truth to say that a case of diabetes in Malta has 38.4 chances of discovery and record to one in Venezuela. Considering that Malta has only about 200,000 inhabitants, and an area of not quite 100 square miles, that it is administered somewhat on the lines of a theoretic benevolent despotism, and that it has been combed over by commissions—mainly for Malta fever—for a generation, the chances of a case of diabetes dying without diagnosis and record are exceedingly minute. In Venezuela, on the contrary, a great many deaths occur without any medical observation. To some degree, islands are more amenable to the gathering of statistics than other areas and the table very clearly shows the influence of concentration of population, civilization and medical organization, particularly the last factor. For instance, in the large European medical centers, we find high rates, with Berlin leading. Comparing cities with cities and for the countries including them, we find inconsistencies in incidence that can scarcely be explained except by differences in statistical accuracy. (For example: London 10.3, Edinburgh 10.4, Isle of Man 18.1, England and Wales 11.8, Amsterdam 15.9, Holland 12.5, Barcelona 11.9, Madrid 8.8, Spain 5.8.) It is possible that more comprehensive statistics would show more definitely differences between city and country, between analogous countries, between different races, between widely different climates, according to dietetic habits, etc. The agreements and divergences in Hoffman's table do not, so far as I can see, demonstrate anything but differences in medical observation and collation of statistics, although there are many tantalizing suggestions that provoke questions as to other factors.

A. L. BENEDICT.

THE SUFFOLK DISTRICT SOCIETIES MEETING ON REHABILITATION.

(Letter by Mr. Joseph A. Parks.)

Boston, Mass., Nov. 27, 1922.

Hilbert F. Day, M.D., 45 Bay State Road,
Boston, Mass.

Dear Doctor:

I have received yours of the 23d and thank you for your kindness in expressing your appreciation to me for the little effort I made at the doctors' meeting the other evening. I assure you it was a pleasure for me to be there and only wish that I had more time to discuss the very important subject of rehabilitation. I was nervous about using up more time than

was allotted to me and did not want to abuse the extraordinary privilege extended to me. At the close of the meeting I should like to have expressed my appreciation to everyone present, particularly to the speakers, for the time and thought which various doctors must have given the subject. It was a grand thing to hear those doctors discuss the best way in which the injured workmen could be assisted and their cases properly handled and made useful members of society. The thing which impressed me most was that all through the entire discussion there seemed to be no thought of "what is there in it for me." The entire keynote of the meeting seemed to be, "how can we help the injured workmen" with no thought as to where the doctor was coming in, financially.

Since that evening, I have felt that I should like to express my thanks in a more public way and felt that they certainly deserve thanks from the injured workmen of Massachusetts and those who will be injured in the future, for the way the medical society in Massachusetts is trying to assist them. I assure you if at any time you should care to have my assistance as a layman, I will gladly give it.

Thanking you for the privilege of being with you on the evening of November 22, I remain,

Sincerely yours,
JOSEPH A. PARKS.

BOSTON CITY HOSPITAL—Staff Clinical Meeting, Cheever Surgical Amphitheatre, Thursday, December 14, 1922, at 8 P.M. Myocarditis, Francis W. Peabody; Mediastinal Tumors, Henry Jackson Jr.; Spastic and Atonic Constipation, Percy B. Davidson. Open discussion. Physicians and students invited. Refreshments served 9:30 P.M. John J. Dowling, *Superintendent*.

BOSTON MEDICAL HISTORY CLUB—Meeting at Boston Medical Library, Monday, December 18, at 8:15 P.M. The proposed amendment to the constitution whereby the annual meeting will be changed from December to April will be voted upon.

Dr. Robert M. Green will read on "The Early History of Medical Journalism in New England." In commemoration of the centenary of the birth of Pasteur (Dec. 27, 1822) Drs. Harvey Cushing, L. J. Henderson and M. J. Rosenau will speak. Dr. M. Storer will show the Pasteur medals in the Storer Collection and there will be an exhibition of Pasteur's works. By vote at the last meeting future meetings will be held on the third Monday of the month, viz. January 15, February 19, March 19, April 16. Please make note of these dates.—John W. Cunnin, *Secretary*.

SOCIETY MEETINGS. DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue.

Barnstable District—Hyannis.—February 2, 1923, (Annual Meeting) May 4, 1923.

Bristol South District—Fall River.—May 3, 1923.

Essex North District—Haverhill, (Semi-Annual Meeting)—January 3, 1923. Y. M. C. A. Building, Lawrence, (Annual Meeting) May 2, 1923.

Meeting of the Suffolk District and the Boston Medical Library at the Library.

December 27, 1922—Surgical Meeting. "Surgical Lesions Occurring in Proctitis—Their Pathology and Management," Dr. Elliott P. Joslin, Boston. An account of the experience in this field of the major hospitals of Boston, by members of the staffs.

January 21, 1923—Medical Meeting. "Epidemic Encephalitis," Dr. E. W. Loring, Boston.

February 28, 1923—Medical Meeting. "Colitis," Dr. Henry F. Hewes, Boston.

March 28, 1923—Surgical Meeting. "A Review of What Surgery Can Accomplish in Diseases of the Thoracic Organs, with a Forecast of the Future," Dr. Howard Lillenthal of New York.

April 25, 1923—Annual Meeting. Election of Officers. "The Record of the Past Twelve Years in Syphilology, with a Forecast of the Future." A series of 10-minute papers. Dr. C. Morton Smith, Boston, will preside.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexis Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, list. The date for each speaker has not been assigned.

Middlesex North District—Meeting, Wednesday, January 31, 1923.

Middlesex East District—Jan. 24, 1923. The Nursing Problem. Speaker to be announced later.

March 21, 1923. Mental Factors in Childhood. Paper by Dr. William Healy.

April 18, 1923. Interpretation of Laboratory Findings. Papers by Dr. E. G. Crabtree and one to be announced later.

May 9, 1923. Annual Meeting.

All meetings except the annual meeting will be held at the Harvard Club in Boston. A. E. Small, *Secretary*.

Worcester District Meetings are scheduled as follows:

January 10, 1923.—The meeting will be held at the Worcester State Hospital, School Street, at 4:15 P.M. Programme: "A Discussion of Status Thyroideus-Lymphatics and the Inherent Compensatory Possibilities," Dr. Walter Timme, New York City. Discussion will be opened by Dr. W. A. Bryan.

February 14, 1923.—The meeting will be held at the Worcester City Hospital at 4:15 P.M. The programme will consist of a series of papers by members of the staff.

March 14, 1923.—The meeting will be held at St. Vincent's Hospital at 8:15 P.M. The programme will consist of a series of papers by members of the staff.

April 11, 1923.—The meeting will be held at Memorial Hospital at 8:15 P.M., and the programme will consist of a series of papers by members of the staff.

May 9, 1923.—Annual meeting and banquet.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

December 26-30, 1922—American Association for Advancement of Science meets in Boston.

December, 1922—Boston Medical History Club will meet December 18, 1922.

January, 1923—Massachusetts Society of Examining Physicians (date and place undecided); Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston; W. H. Allen, Mansfield, Mass., Secretary.

January, 1923—Boston Association of Cardiac Clinics. Meeting January 18, 1923, at 8:15 P.M. Boston Lying-In Hospital (New Hospital). Subject: Pregnancy and Heart Disease.

January, 1923—Boston Medical History Club will meet January 15, 1923.

February, 1923—New England Dermatological Society Meeting, February 14, 1923, at 3:30 P.M., in the Skin Out-Patient Department, Massachusetts General Hospital; C. Guy Lane, Secretary.

February, 1923—Boston Medical History Club will meet the third Monday of this month.

March, 1923—Massachusetts Society of Examining Physicians (date and place undecided); Hilbert F. Day, Secretary.

March, 1923—Boston Association of Cardiac Clinics. Meeting March 15, 1923, at 8:15 P.M. Boston City Hospital. Subject: Prevention and Relief of Heart Failure.

March, 1923—Boston Medical History Club will meet the third Monday of this month.

April, 1923—New England Dermatological Society Meeting, April 11, 1923, at 3:30 P.M., in the Surgical Amphitheatre, Boston City Hospital; C. Guy Lane, Secretary.

Massachusetts Association of Boards of Health, April 26, 1923, Boston; W. H. Allen, Mansfield, Mass., Secretary.

April, 1923—Boston Medical History Club will meet the third Monday of this month.

May, 1923—Massachusetts Society of Examining Physicians (date and place undecided). American Pediatric Society Meeting, May 31, June 1 and 2, 1923, at French Lick Springs Hotel, French Lick, Ind.; H. C. Carpenter, Secretary.

May, 1923—Boston Association of Cardiac Clinics. Meeting May 17, 1923, at 8:15 P.M. Children's Hospital. Subject: Rheumatism and Chloroma and Heart Disease.

June, 1923—American Medical Association, San Francisco, June 2-29, 1923; Alexander R. Craig,* Chicago, Ill., Secretary.

July, 1923—Massachusetts Association of Boards of Health, July 26, Nantasket; W. H. Allen, Mansfield, Mass., Secretary.

*Deceased September 2, 1922.

STUDIES IN PANCREATIC FUNCTION. THE ENZYME CONCENTRATION OF DUODENAL CONTENTS IN PATHOLOGICAL CONDITIONS INVOLVING THE PANCREAS, LIVER AND STOMACH.

BY CHARLES W. MCCLURE, M.D., BOSTON,
and

CHESTER M. JONES, M.D., BOSTON.

[From the Evans Memorial, the Massachusetts General Hospital, the Peter Bent Brigham Hospital and the Massachusetts Homeopathic Hospital.]

Numerous clinical studies¹ have been made of enzymatic activity in the stools, urine and duodenal contents, in an effort to obtain a satisfactory measure of the activity of the external secretory function of the pancreas. The results of such investigations have led observers to maintain that obstruction of the pancreatic ducts is accompanied by marked diminution in proteolytic, amylolytic and lipolytic activity in duodenal contents, and in the amylolytic activity in stools, while the amylolytic activity in urine was observed to be increased. Critical examination of the methods used in all such studies, however, has shown them to be far from accurate, and subject to large degrees of individual error. By such methods it was demonstrated that the amylolytic activity in both urine and

stools varied greatly in persons without pathological involvement of the pancreas, and diagnostic deductions based upon such estimations were of little or no clinical significance.²

The relative inaccuracy of all methods for estimating enzymatic activity, that have been employed in studying cases of supposed pancreatic insufficiency, is recognized. The fallacy of drawing conclusions from data obtained by them rendered desirable the development of newer methods, which would conform with the present-day concepts of the physical chemistry of enzyme action. The recent work of McClure, Wetmore and Reynolds³ has made possible the application of more refined technic to the study of external pancreatic function, and has eliminated many of the obvious sources of error in previous methods. The methods devised by these investigators conform to the newer concepts of enzyme action, and they take into account certain previously disregarded factors, such as the influence of buffer conditions and of hydrogen ion concentration on enzyme action, lack of uniformity of enzymatic activity, lack of stability of enzyme action, etc. These workers studied, by means of these methods, a series of fifteen normal individuals,⁴ determined the approximate accuracy of the methods, and found the normal variation and lower normal limits of enzyme action in the duodenal contents. These findings were later confirmed by further observations on normal persons and patients without demonstrable pancreatic disease.*

*Unpublished observations.

It is the purpose of this paper to present the findings obtained by the use of the above methods as applied to a series of selected cases, consisting largely of acute or chronic involvement of the pancreas or biliary tract. We shall attempt to consider, first, the pathologic physiology existing in cases of pancreatic disease, and second, the practical clinical value of the above tests of enzymatic activity, as a means of diagnosis and prognosis. Studies of the enzymatic activity in the duodenal contents have been made in patients with pernicious anemia, achylia gastrica, chronic colitis, carcinoma of the liver and bile ducts, carcinoma of the pancreas, acute and chronic pancreatitis, and in patients with jaundice from other causes.

Technic.—The method of procedure for obtaining duodenal contents has been described in a previous article.⁴ In brief, it consists in allowing the duodenal tube to pass into the second portion of the duodenum and verifying its position by fluoroscopy. The patient then drinks a mixture consisting of 40 c.c. of 20 per cent. cream (ordinary heavy cream) in which is suspended 15 grams of barium sulphate. The barium is added because it has been found that cream often appears in the duodenal contents more quickly when mixed with barium than when given alone. After ingesting the cream and barium mixture the patient lies on the right side, and the flow of duodenal contents is initiated by gentle suction with a syringe. As soon as the flow has started, the duodenal contents are allowed to siphon off, and are collected for one hour after barium appears in the duodenal contents.

The estimation of enzymatic activity is made,

within an interval of not more than eighteen hours after collecting the duodenal contents, by the methods devised by McClure, Wetmore and Reynolds.³ How much longer than eighteen hours the enzymes remain stable has not been determined. Proteolytic activity is estimated by allowing a dilution of the duodenal contents to act on a solution of soluble casein. The casein not affected by proteolytic action is precipitated by means of metaphosphoric acid solution. The index of proteolytic activity is taken as the number of milligrams of nitrogen not precipitated by the metaphosphoric acid. This nitrogen value is determined by an adaptation of the method of Folin and Wu for the determination of non-protein nitrogen in the blood. Amylolytic activity is estimated as the number of milligrams of glucose developed by action of duodenal contents on a solution of soluble starch. The index of amylolytic activity is taken as the total number of milligrams of glucose developed, as determined by the method of Folin and Wu for the determination of sugar in the blood. Lipolytic activity is estimated by allowing duodenal contents to act on a true emulsion of cottonseed oil, and determining the amount of acidity developed by titrating with tenth normal alcoholic solution of NaOH. The total number of c.c. of N/10 NaOH necessary to neutralize the acidity developed is used as the index of lipolytic activity. The samples of duodenal contents and the reagents used must be controlled for the presence of nitrogen not precipitated by metaphosphoric acid, for copper reducing bodies and for acidity. In a certain number of cases it was found that the duodenal contents obtained both from patients and from

normal subjects were so viscid that pipetting was difficult. The results obtained, however, in examining such specimens were entirely comparable to those obtained in cases in which the viscosity was not excessive. The extremely viscid duodenal contents were diluted as called for by the method for estimating amylolytic activity, and filtered through dry filter paper. With this precaution the final blue solution was not turbid.

Examination of Cases.—The enzymatic activities of duodenal contents obtained from four patients with achylia gastrica were estimated. Two of these patients presented the clinical entity achylia gastrica, with chronic diarrhoea, and two, pernicious anemia in severe relapse. A fifth patient was studied who was

suffering with chronic colitis. The findings in these cases, together with the minimum normal limits of enzymatic activity in duodenal contents as determined in normal individuals, and in patients without pancreatic disease, are outlined in the following table (Table 1). Study of these results show that the activities of the various types of enzymes in the duodenal contents were well above the minimum normal limits. The significance of these findings will be discussed later.

The enzymatic activities in the duodenal contents obtained from patients with some form of pancreatic disease were next studied. The findings are outlined in Table 2. All but two of the patients included in this group underwent an exploratory laparotomy during their

x-exploratory laparotomy. a-autopsy

stay in the hospital, or were examined at autopsy. Of the two cases not so examined one was clinically cancer of the head of the pancreas, and the other was a case of severe diabetes mellitus.

In Table 2 the enzymatic activities of the duodenal contents from Cases 6, 7, 10 and 16 were above the minimum normal limits. The duodenal contents in Cases 6, 7 and 10 were obtained about two weeks after laparotomy. Case 6 was one of cyst of the pancreas. The situation of the cyst was such that there was very little involvement of the pancreatic parenchyma, and no obstruction of the duct of Wirsung. At laparotomy in Case 10 two necrotic areas were found on the surface of the pancreas, but the greater part of the pancreatic parenchyma was not demonstrably diseased. Exploration in Case 7 showed the tail and body of the pancreas to be largely replaced by carcinomatous tissue. The head of the pancreas, however, was not involved, and there was no obstruction to the pancreatic duct. Case 16 represented extremely severe diabetes mellitus. The patient had lost fifty-six per cent. of his usual body weight.

The enzymatic activities of the duodenal contents of Cases 8, 9, 11, 12, 13, 14 and 15 were for the most part abnormally low. The clinical records of these cases will be found in the section of this article entitled Case Reports. Case 8 was clinically cancer of the head of the pancreas and obstruction to the pancreatic duct could explain the diminished enzymatic activity, but no operative or autopsy confirmation of the diagnosis was obtainable. Case 9 was one of carcinoma of the head of the pancreas, diagnosed at operation. The duodenal contents from this case showed negligible degrees of proteolytic and lipolytic activity, but amylolytic activity was well above the minimum normal limit. Case 11 was admitted to the hospital with a provisional diagnosis of possible pancreatic tumor. Studies of the duodenal contents showed a diminution of the three types of enzyme action. At operation chronic gall-bladder disease was found, and, also, one small stone in the cystic duct. In addition the pancreas was exceedingly hard throughout, and gave grossly the typical finding of chronic interstitial pancreatitis. Case 12 was one of hemochromatosis, with chronic pancreatitis. At autopsy it was observed that the pancreatic parenchyma was not greatly fibrosed, so that the diminished enzymatic activities found were not the result of great anatomical destruction of pancreatic tissue.

The first specimens of duodenal contents were obtained from Cases 11 and 15, about two weeks after laparotomy. Both these patients presented cases of acute hemorrhagic pancreatitis with extensive involvement of the pancreatic parenchyma. In the first specimen of duodenal contents obtained from Case 11, the proteolytic and lipolytic activities were just below the minimum normal limit, while amylolytic activity was above this limit. Nineteen days later a second

specimen of duodenal contents showed proteolytic activity well above the minimum normal limit, while lipolytic and amylolytic activities were much decreased below normal. The enzymatic activities of the first specimen and of the second specimen (obtained five weeks later) from Case 15, were both below the minimum normal limits. A third specimen was procured two weeks after the second. The proteolytic activity in this third specimen was above the minimum normal, lipolytic activity was slightly reduced, and amylolytic activity was much below the normal. The fourth specimen was taken five months after operation. The patient was in fair physical condition, but the examination of the duodenal contents showed a further decrease in all the enzymatic activities. In both these cases it was found that in the same specimen of duodenal contents one type of enzymatic activity was above the minimum normal limit, while the other two types were below this limit, and that the discrepancy was well marked.

Case 13 was one of unusual interest, inasmuch as it represented the progress of a case of pancreatitis from the acute stage to the final condition resulting in complete chronic involvement of the gland. The analysis of the duodenal contents was made about seven years following the original attack, during which laparotomy was performed and drainage instituted. Six months following operation about two-thirds of the pancreas is said to have sloughed away, and there has been a fistula persisting to date. At the time of the collection of the duodenal contents the patient had an acute, severe diabetes. No enzymatic activities of the duodenal contents could be demonstrated.

The effect of pancreatic disease on the enzymatic activities of duodenal contents may be summarized from the results outlined in Table 2, as follows:

1. Extensive involvement of the pancreatic parenchyma due to acute pancreatitis, or less extensive pathology accompanying chronic pancreatitis, was associated with a decrease below the minimum normal limits of at least two of the three types of enzymatic activity in the duodenal contents. It is possible that the diminution in enzymatic activity in these cases is due, in part, to obstruction to the flow of pancreatic secretion by the pathological process, as well as to actual destruction of pancreatic parenchyma.

2. Cancer of the head of the pancreas produced a marked decrease in enzymatic activities; although extensive carcinomatous involvement of the pancreas, not involving the head or duct of Wirsung, did not demonstrably affect the enzymatic activities of duodenal contents.

3. Slight involvement of the pancreatic parenchyma, when due to acute pancreatitis, pancreatic cyst or severe diabetes mellitus did not affect the enzymatic activities of the duodenal contents.

The enzymatic activities of duodenal contents obtained from fourteen patients with va-

rious types of disease of the biliary system, in- studied. The results are outlined in the follow-
cluding toxic and infectious jaundice, were next ing table. (Table 3).

x = Exploratory laparotomy

In Table 3 the enzymatic activities of duo-
denal contents from Cases 17, 18, 19, 20, 27 and
28 were not below the minimum normal limits,
with the exception of a slight reduction in the
amylolytic activity of Cases 18 and 27. At the
time duodenal contents were collected all of the
patients were jaundiced, except Case 26. Cases
17, 18 and 19 underwent laparotomy; Cases 20
and 28 were not operated. The preoperative
diagnosis of Cases 17 and 18 was cancer of the
pancreas. At laparotomy, however, no evidences
of cancer were found anywhere in the upper

abdominal region. The duodenal specimen for
enzyme studies was obtained from Case 20 after
several instillations of 33 per cent. magnesium
sulphate solution, given at weekly intervals. It
will be noted that in this specimen proteolytic
and lipolytic activities were markedly great.

Abnormally low findings were present in duo-
denal contents obtained from Cases 21, 22, 23,
24, 25, 26, 29 and 30. The diagnosis given in
the table represents the conditions found on
laparotomy in all cases, except Cases 29 and 30.

All duodenal contents were obtained prior to operation except from Case 25.

No bile was present in the first specimens of duodenal contents obtained from Cases 23 and 24, but second specimens obtained a few days later contained much bile. In the interim between collection of the first and second specimens, Cases 23 and 24 had received duodenal lavage with magnesium sulphate solution. The first specimens of duodenal contents obtained from these cases after lavage with magnesium sulphate also contained no bile, although much bile was present in specimens taken on later dates. From such findings it is fair to conclude that obstruction to the flow of bile and pancreatic juice existed at the time of collection of the first specimens of duodenal contents. In this connection it is to be recalled that at operation Case 24 showed a stone in the ampulla of Vater.

Stones were found in the ampulla of Vater in Case 22, and a partial obstruction caused by them might explain the low enzymatic activities present in the first specimen of duodenal contents. The second specimen of duodenal contents from this case was obtained a few days later, and in the interim duodenal lavage with magnesium sulphate solution had been employed. In the second specimen the enzymatic activities were all above the lower limits of normal.

Case 25, which was explored several weeks prior to a study of the duodenal contents, showed at operation a mass of inflammatory tissue in the region of the gall-bladder, containing several gallstones. It was impossible to explore the common bile duct or the region of the pancreas. The low figures for enzymatic activity can probably best be explained by an inflammatory process involving the common bile duct, and to some extent the pancreatic duct. In Case 26 there was no jaundice, and no obstruction to the flow of bile existed at the time of operation. The low lipolytic and amylolytic activities in this case, therefore, cannot be explained as resulting from obstruction to the pancreatic duct; it will be noted that proteolytic activity was not below the minimum normal limit.

The specimens of duodenal contents obtained from Case 20 showed abnormally low proteolytic values, while the figures for lipolytic and amylolytic activity were above the minimum normal limits. These findings are not comparable to those found in the cases in which obstruction to the pancreatic duct was proved to exist, but are similar to the findings in those cases in which pancreatic disease existed (cf. Cases 12 and 14 in Table 2). Furthermore, Case 21 was not jaundiced at the time the second specimen of duodenal contents was collected. The significance of the findings will be discussed later.

The first specimen of duodenal contents was taken from Case 29 at a time when the contents obtained from the use of magnesium sulphate showed only a faint yellowish tinge. In this

specimen only the proteolytic activity was below normal. A few days later the duodenal contents, following the use of magnesium sulphate, were deep golden yellow. At this time proteolytic activity was normal, while lipolytic and amylolytic values were slightly below the minimum normal limits. In Case 30 there had been almost complete absence of bile from the duodenal contents after magnesium sulphate lavage up to a few days prior to obtaining the specimen for enzyme studies. This latter specimen contained much bile, and proteolytic and lipolytic figures were normal. Amylolytic activity was much below normal. The significance of all the above findings will be discussed at the close of the paper.

The findings outlined in Table 3 may be summarized as follows:

1. Partial or apparently complete absence of bile did not in itself diminish the enzymatic activities of the duodenal contents below the minimum normal limits, when no obstruction to the pancreatic duct existed.
2. Obstruction in the ampulla of Vater was accompanied by diminished enzymatic activities of duodenal contents.
3. Diminished activity of one or more of the enzymes was found in the duodenal contents of two patients without obstruction to the pancreatic duct demonstrable at operation.
4. Toxic jaundice due to arsphenamin was not accompanied by abnormally low enzymatic activities of duodenal contents.
5. Diminished activity of one or more of the enzymes was found in the duodenal contents of two patients with infectious (catarrhal) jaundice.

Discussion.—From the standpoint of the present concepts of the physiology of digestion, as expressed in the various standard works on physiology, there are a vast number of hypothetical entities in the human intestines which can affect enzyme action. Absence of tryptic activity, for example, could theoretically be due to a lack of enterokinase, so that "trypsinogen" would not be changed into the active form, trypsin. The existence of enterokinase, however, has not been definitely proved,⁵ and the same may be said of other hypothetical substances said to affect enzyme action. The great majority of these substances may have no actual existence, but may be merely the expression of certain physical chemical conditions under which enzymes act less or more efficiently. For this reason the so-called "inhibitors," "accelerators" and "activators" of enzymes will not be discussed in the interpretation of the results obtained in the work here reported. Another element of importance in interpreting the results presented in this study is the question as to inherent errors in the methods employed. The large amount of work done on normal persons and patients without pancreatic disease has satisfactorily controlled the methods and procedures, and we consider that no inherent er-

rors exist which vitiate conclusions drawn from a comparison of the results obtained in the work here presented with the findings obtained in normal individuals.

The results given in Table 1 show that normal enzymatic activities were present in duodenal contents of the patients with no detectable hydrochloric acid in the gastric contents (usual test with Töpfer's reagent). If achlorhydria-gastrica existed in these patients, obviously the secretion of pancreatic juice was not dependent on the presence of hydrochloric acid injected into the duodenum from the stomach. The findings also show that pancreatic achylia did not exist, although it is frequently stated that pancreatic insufficiency is present in both achylia gastrica and pernicious anemia.

The duodenal contents of two of the patients in this series (Cases 17 and 28) apparently contained no bile. Nevertheless, the enzymatic activities were not below the minimum normal limits. In one of these patients (Case 17) laparotomy findings demonstrated no obstruction to the pancreatic duct and no disease of the head of the pancreas. In the other patient (Case 25) it seems fair to assume that neither of these conditions existed. Furthermore, the addition of human bile to duodenal contents does not increase the enzymatic activities.* From these findings it is assumed that the character of the methods used is such as to eliminate bile as a conditioning factor in enzyme activity. This conclusion is not to be construed as meaning that the action of pancreatic enzymes is not affected by the presence or absence of bile in the human intestines, but only *in vitro*, under the experimental conditions called for by the methods used in the work here reported.

The findings in Case 10, in Table 2, show that acute necrosis involving but little of the pancreas did not demonstrably affect the enzymatic activities of the duodenal contents. From this it seems reasonable to infer that the secretory activity of the pancreas was not greatly disturbed. Cases 14 and 15, on the other hand, showed greatly altered enzyme activity, and in these cases extensive destruction of pancreatic parenchyma had occurred. These findings indicate that the degree of abnormality in enzymatic activities present in duodenal contents obtained from cases of acute pancreatitis depends largely on the amount of destruction of pancreatic tissue.

Cases 14 and 15 represented acute pancreatitis. In the duodenal contents from these cases there was dissociation of enzymatic activities; *i.e.*, one or more types of enzymatic activity were of normal degree, while the remainder were below the minimum normal limits. Such findings did not occur in any of the duodenal contents obtained from a relatively large number of normal persons and patients without demonstrable pancreatic disease. For this reason the results obtained in Cases 14 and 15, in which there was

extensive pancreatic disease at the time of laparotomy, are interpreted as resulting from pancreatic dysfunction.

In Cases 8 and 9 (Table 2) (cancer of head of the pancreas) the pancreatic ducts were considered to be occluded by the carcinomatous process. With one exception, the enzyme activities were considerably diminished. The exception noted occurred in the value for amylolytic action in Case 9. The activity of this enzyme may be explained either as a result of an amylase arising in the pancreas and gaining access to the duodenum through ulcerative processes, or as coming from the saliva or duodenal mucosa. In any event, the findings in these two cases indicate that in the presence of cancer of the head of the pancreas the enzyme action of the duodenal contents will be notably diminished.

The result obtained in Case 7 (cancer of body and tail of pancreas) shows that cancer of the pancreas not involving the head of that organ did not produce achylia pancreatica, although about two-thirds of the pancreatic parenchyma were destroyed.

The findings at operation in Case 11 make the diagnosis of chronic pancreatitis seem certain; and the enzymatic activities of both specimens of duodenal contents were very little.

Autopsy and histopathological findings in the case of hemochromatosis (Case 12) demonstrated that the greater part of the pancreatic tissue was anatonically intact, although there was definite sclerosis and abnormal pigment deposition. Nevertheless, the enzymatic activities of the duodenal contents were depressed much below the minimum normal limits. These findings indicate that the depression in the secretory activity of the pancreas was partly the result of a functional disturbance. Case 13 was also one of chronic pancreatitis. The clinical findings in this case show that the pancreatic parenchyma had been extensively destroyed, and it seems warranted to conclude that but little external secretory activity remained. This explains the absence of enzymatic activities from the duodenal contents. The enzymatic activities of the duodenal contents from these three cases were all very low. These findings show that the external secretory function of the pancreas was depressed.

From the above discussion it would seem justifiable to conclude that the study of enzymatic activities of duodenal contents, ascertaining the activity of the external secretory function of the pancreas, may be of distinct value: 1, in diagnosing chronic pancreatitis; 2, in locating the site of the lesion in cancer of the pancreas; 3, in estimating the amount of destruction of pancreatic parenchyma in acute necrosis of that organ.

The findings in Cases 17, 18, 19, 20 and 28 of Table 3 show, that in the presence of obstruction to that portion of the bile duct lying proximal to the pancreatic duct, and in the absence

*Unpublished observations.

of pancreatic disease, no abnormalities in the enzymatic activities of the duodenal contents were demonstrable. When obstruction to the pancreatic duct (Cases 22, 23 and 24 of Table 3) existed, enzymatic activities of the duodenal contents were much below the minimum normal level. Such results indicate that the study of duodenal enzymatic activities may furnish laboratory findings of definite value in locating a lesion causing obstructive jaundice.

Duodenal contents were taken from Case 8 (cancer of the head of the pancreas) after the employment of magnesium sulphate solution on several occasions. It will be recalled that enzymatic activities in this case were much diminished, and that the duodenal contents apparently contained no bile. In Cases 22, 23 and 24 (stone in the ampulla of Vater), on the contrary, magnesium sulphate lavage was followed by marked increase in the bile content and the degree of enzyme action in the duodenal contents. In these cases the use of magnesium sulphate lavage, combined with study of enzymatic activities, of the duodenal contents gave findings in the presence of benign obstruction which were different from those obtained when the obstruction was of malignant character. The differences were so marked as to suggest that results obtained from the combined use of duodenal lavage and enzyme concentration studies will prove to be of value in differentiating between the two types of obstruction.

In obstructive jaundice the question frequently arises as to whether the cause is benign or malignant. The three most frequent sites of malignant disease causing jaundice, are primary cancer of the head of the pancreas, primary cancer of the biliary passages, and cancer of the liver secondary to gastric carcinoma. Cancer of the stomach can almost invariably be demonstrated by x-ray examination; cancer of the bile ducts will not usually allow bile to flow into the duodenum (Case 25); and cancer of the head of the pancreas will usually occlude the pancreatic duct and largely exclude pancreatic enzymes from the duodenal contents. Thus the estimation of the enzymatic activities of the duodenal contents would seem to be of distinct value in the diagnosis of suspected cancer of the biliary tract or of the head of the pancreas.

As we stated in the body of the paper, it was not proved that a stone or inflammatory swelling of the ducts did not obstruct the pancreatic flow in Case 25. For this reason the cause for abnormal enzymatic activities found in this case cannot be definitely given. At operation it was impossible to locate the common bile duct or pancreas on account of the diffuse inflammatory process involving the entire biliary tract. In Case 26, however, the clinical findings were quite different. This patient was not jaundiced at any time and no obstructive lesions were demonstrable on laparotomy. No obstruction to the pancreatic duct was demonstrable, and the abnormal enzymatic activities present

in the duodenal contents were probably the result of some other cause than parenchymatous destruction. It will be remembered that there was dissociation of enzymatic activities in this case, as well as in Cases 21, 29 and 30. These findings are comparable to those occurring in acute pancreatic necrosis (Cases 14 and 15) in which there was undoubtedly derangement of the external secretory function of the pancreas. For this reason it is considered probable that similar derangement existed in Cases 21, 26, 29 and 30, but until further experimental evidence is available, an exact interpretation of these anomalies cannot be made.

The results obtained in studying Case 15 (acute pancreatitis) suggests definitely that periodic estimations of enzymatic activities in the duodenal contents furnish a rational method of following the progress of cases of pancreatic insufficiency.

The question arises as to the need for the rather complicated and time-consuming processes of obtaining duodenal contents and of estimating their enzymatic activities. It has been urged that any secretory anomalies of the pancreas would be reflected in the stools, and that the examination of the stools would suffice. That such is not necessarily the case is evident from the findings in Case 11 (chronic pancreatitis) in which careful stool examinations were made on successive days following a Schmidt test diet.

All the examinations were negative. In several of the other cases here reported the stool examinations on house diet showed no evidences of abnormal digestion. In cases with a low sugar tolerance, furthermore, it is obviously inadvisable to feed proper test diets for satisfactory stool examination. Also, examination of stools will be of no aid in the diagnosis of pancreatic disease when bile is excluded from the intestines or when pathological conditions prevent the absorption of food from the small intestines. In addition, it is well known that bacteria always present in human intestines can duplicate all phases of enzyme digestion, so that it is conceivable that bacterial action alone could mask evidences of pancreatic disease as obtained from stool examination. In this connection it is of interest to note that McClure, Vincent and Pratt⁶ found that completely depancreatized dogs could often utilize a considerable percentage of protein and fat of food ingested. It seems clear, therefore, that pancreatic disease may not be evidenced by stool findings alone. In selected cases, therefore, the use of the methods described and used in this work will be found of aid in diagnosis and in following the progress of a given case.

CONCLUSIONS.

1. Abnormalities in enzymatic activities of duodenal contents, demonstrated by the methods and procedures used in the work here reported, were found: (a) in the presence of some organic lesion involving the pancreas primarily or sec-

ondarily; or (b) when clinical, operative or autopsy findings indicated the possibility of derangement of the external secretory function of the pancreas. It seems fair to assume, therefore, that such abnormalities show pathological involvement of the pancreas or its ducts, and that the involvement of the pancreas may be mechanical or functional in nature. If this assumption is correct, then it is justifiable to conclude that estimation of enzymatic activities of duodenal contents furnishes an index to the activity of the external secretory function of the pancreas.

2. In achylia gastrica and pernicious anemia no abnormalities in the activity of the external secretory function of the pancreas were demonstrable, as measured by the enzyme concentration of duodenal contents. These findings suggest that the presence of hydrochloric acid is not necessary in order to stimulate normal pancreatic secretory activity.

3. Under the experimental conditions used, enzymatic activity was not demonstrably affected by the presence or apparent absence of bile in the duodenal contents.

4. The external secretory function of the pancreas, as measured by the enzyme concentration of duodenal contents, was found to be much depressed in chronic pancreatitis.

5. Acute pancreatic necrosis, cancer of the head of the pancreas and lesions obstructing the pancreatic duct were accompanied by marked abnormalities in enzymatic activities of duodenal contents. Obstructive lesions caused great diminution, while acute necrosis usually caused dissociation in enzymatic activities.

6. Estimation of enzymatic activities of duodenal contents furnished findings of value in the differential diagnosis between benign and malignant lesions, causing obstructive jaundice.

7. Dissociation of enzymatic activities of duodenal contents are interpreted as showing derangement of the external secretory function of the pancreas.

8. Acute and chronic cholecystitis and infectious (catarrhal) jaundice were accompanied by dissociation of enzymatic activities of duodenal contents. This finding suggests that there was associated derangement of the external secretory function of the pancreas.

CASE REPORTS OF IMPORTANCE IN AIDING THE READER IN THE INTERPRETATION OF THE EXPERIMENTAL RESULTS HERE REPORTED ARE APPENDED.

CASE No. 7.—A. T., male, aged 18. E. S. 248869.

Admitted to Massachusetts General Hospital March 31, 1922, and discharged April 29, 1922.

Diagnosis: Carcinoma of pancreas (not involving the head). Diabetes mellitus (mild).

At operation the tail and body of the pancreas were found to be largely invaded by carcinoma. However, the head of the pancreas

was not involved and there was no demonstrable obstruction to either the pancreatic or bile ducts.

CASE No. 8.—W. E. H., male, aged 49. Med. No. 14946.

Admitted to Peter Bent Brigham Hospital December 7, 1921, and discharged December 31, 1921.

Diagnosis: Cancer of head of the pancreas.

Patient was a man 49 years of age, whose past medical history is essentially negative. During the past 18 months prior to admission to the hospital the patient had been troubled with malaise, lassitude and physical weakness. Jaundice had been present seven months. Onset had been painless and associated with dyspepsia, diarrhoea and excessive thirst. On physical examination the patient showed deep icterus and was much emaciated. The liver was markedly enlarged, the left lobe measuring 1.5 cm. below the costal margin in the midclavicular line. The surface of the liver was smooth and the edge firm. In the right upper quadrant, below the liver edge, a smooth, firm mass about the size of a lemon was palpable.

X-ray studies showed no abnormalities in the gastrointestinal tract.

Clinical examination of the blood showed a moderate degree of secondary anemia. Gastric analysis showed normal acidity. The urine and stools were those usually found in obstructive jaundice. Operation was refused.

CASE No. 9.—J. E. T., male, negro, aged 56. Med. No. 19653.

Admitted to Peter Bent Brigham Hospital May 22, 1922, and transferred to Surgical Service May 30, 1922.

Diagnosis: Carcinoma of head of pancreas (involving the common bile duct).

Past Medical History was essentially negative. The present illness began six weeks prior to admission to the hospital. During the first two weeks there were gaseous bloating of the epigastrium and epigastric distress at night; relieved by soda or hot water. The taking of food caused dull aching in the epigastrium, beginning five to ten minutes after eating and lasting from three to twelve hours. Jaundice developed four weeks prior to admission to the hospital, and was accompanied by pruritus and profuse sweats. Lying on the right side caused nausea. Slight dyspnoea had been present since the onset.

On physical examination the sclerae and skin were deeply jaundiced. The liver edge was palpable 5 cm. below the right costal margin; it was firm and irregular. There was moderate tenderness in the epigastrium, more particularly just to the right of the midline. There was right inguinal hernia. Otherwise the physical examination was negative.

Fluoroscopic examination demonstrated a concave defect in the outline of the lesser curvature

side of the antrum and first portion of the duodenum. This finding suggested pressure from without.

Hemoglobin was 88 per cent., white blood cells 9,000 and red cells 4,000,000 per c.mm. The smear was not unusual. Wassermann reaction was negative. Gastric analysis showed a moderately low free HCl and total acidity. Benzidin test was negative. The findings in the urine and stools were those usual in obstructive jaundice. At operation a large adenocarcinoma of the head of the pancreas, involving the common bile duct, was found.

CASE No. 10.—E. S. R., male, aged 40. W. S. 248407.

Admitted to Massachusetts General Hospital March 8, 1922, and discharged April 29, 1922.

Diagnosis: Acute pancreatitis. Chronic cholecystitis. Cholelithiasis.

The patient entered the hospital complaining of attacks of epigastric pain, vomiting and jaundice and of constipation. The past history was essentially negative.

During the past four years prior to admission to the hospital the patient had had attacks of severe epigastric pain, lasting about seven to twenty-four hours and accompanied by repeated vomiting of foul, greenish material, and by constipation. Such attacks occurred at intervals of four or five months. In one attack jaundice had occurred. The present attack had developed ten days before admission. The pain was paroxysmal in character, sharp in nature and located in mid-epigastrium. The bowels were constipated.

On physical examination moderate tenderness and muscular rigidity were found in the left upper abdominal quadrant, in the region of the gall-bladder. The patient was definitely jaundiced. X-ray of gall-bladder region showed shadows suggesting biliary calculi.

Laboratory findings: Hemoglobin was 85 per cent. and white cells 10,000 per c.mm. The Wassermann was negative. The findings of the stomach contents after an Ewald breakfast were normal. The stools were not abnormal and contained bile.

March 14. Operative note: The gall-bladder wall was thickened and showed an area of fat necrosis (also demonstrated microscopically in sections). The gall-bladder contained two stones and much dark fluid. The pancreas was found to contain areas of necrosis and the gastro-colic omentum showed areas of fat necrosis.

CASE 11.—F. H., male, aged 50. E. S. 250706. Admitted to Massachusetts General Hospital July 9, 1922.

Diagnosis: Chronic cholecystitis. Cholelithiasis. Chronic pancreatitis.

Patient entered the hospital complaining of epigastric pain and loss of weight.

The past history was essentially negative. Venereal infection was denied.

Present Illness: For the last six months the patient had suffered from attacks of epigastric pain, non-radiating, coming on at intervals of several days to weeks, with no apparent relation to meals. Pain was not severe until recently, did not cause vomiting, and was not severe enough to make the patient cry out. It never waked the patient up. It was relieved at first by walking about, but recently not relieved by ordinary procedures. There had been no jaundice, hematemesis, melena, urinary abnormalities.

During the last few weeks prior to admission, attacks have occurred several times daily, and have lasted from half an hour to several hours. There was no diarrhea or constipation. During the last six months the patient had lost about thirty pounds in weight.

Physical Examination: Well developed somewhat emaciated man. Skin very dark, where it had been exposed to sun and heat, but no abnormal areas of pigmentation. In the mid-epigastrium there was an indefinite mass, which was tender, not movable, pulsating but not expansile. In the right upper quadrant there was increased muscular resistance, but no definite mass was palpable.

Laboratory Findings: Blood and urine were essentially negative. The blood Wassermann was negative. Examination of the stools following a full Schmidt test diet was absolutely negative. X-ray examination of the gastrointestinal tract failed to show any abnormal findings, except that the stomach seemed to be pushed somewhat forward as if a mass was behind it. Barium enema was negative.

Operation: At operation a large, thickened gall-bladder was found, with a single stone in the cystic duct. The pancreas was enlarged and extremely hard throughout, and on palpation it seemed typical of advanced interstitial pancreatitis.

CASE 12.—J. E. O'M. Male, aged 43. E. M. 248570.

Admitted to the Massachusetts General Hospital March 15, 1922, and died April 4, 1922.

Diagnosis: Hemochromatosis. Chronic pancreatitis. Syphilis. Diabetes mellitus. Hypertrophic cirrhosis of the liver. Acute colitis. Bronchopneumonia.

Patient entered the hospital complaining of epigastric pain, dizziness, faintness, weakness and cough.

The patient has been a moderate user of alcohol. At the age of 18 he had pneumonia. Eighteen years prior to admission he had a bubo in the left groin. Nine years prior to admission a hard chancre developed on the penis, but no antiluetic treatment had been taken. No secondary eruption had been observed. Eight years ago there had been an attack of acute

arthritis, and, during the same year, an attack of malaria.

Present Illness: For ten years there had been vague, indefinite epigastric "pain" about 30 minutes after dinner and supper, lasting five to ten minutes. The "pain" radiated to the left axillary region and to the back. The "pain" occurred three or four times a week and was associated with nausea, occasional vomiting, and always with dizziness, faintness and weakness. During the two weeks prior to admission the epigastric pain had disappeared. For two months prior to admission the patient had an excessive appetite, marked thirst, polyuria and loss in body weight from 158 to 124 pounds. Two years prior to admission his family physician discovered glycosuria. In December, 1921, the patient had fractured a rib. Since then there had been a distressing cough which was unproductive until a week before admission. During this time sputum was raised. There had been no hemoptysis, but during the two weeks prior to admission night sweats had occurred.

Physical Examination: Emaciated. Skin dark, but no definite areas of pigmentation. Liver definitely enlarged, edge smooth.

Laboratory Findings: The hemoglobin was 70 per cent. White blood cells were 8000 per c.mm. Blood sugar was 0.3 per cent. on admission, but dropped to 0.1 per cent. on starvation. The blood Wassermann was positive.

On admission the 24-hour output of urine was between 3000 and 4000 c.c., and contained about 7 per cent. glucose. Under treatment the 24-hour amount dropped to 1000 to 1500 c.c. and the glucose to 1 to 2 per cent. With onset of fever, acetone and diacetic acid appeared in the urine. All stools examined were the result of enema. These stools contained much pus and mucus.

During his stay in the hospital diarrhoea developed, and later bronchopneumonia, of which the patient died. Duodenal specimen was obtained on the day before onset of diarrhoea, and before the patient's condition became dangerous.

Autopsy Findings were typical of hemochromatosis, with marked pigmentation and fibrosis of the liver and pancreas.

CASE 13.—D. C. White, male, aged 54. E. M. 205738.

Admitted to Massachusetts General Hospital June 10, 1922.

Diagnosis: Chronic pancreatitis. Diabetes mellitus. The past history was essentially negative.

During the year 1915 the patient had had dull epigastric pain, coming on two or three times a week and occurring 30 minutes after the midday meal. The pain was relieved by hot water. At the end of this year, one morning, just after breakfast, the patient was seized

suddenly with severe, colicky epigastric pain, requiring morphine for its relief. This pain radiated around both hypochondriac regions to the back. It persisted for several days. The patient was then admitted to the Massachusetts General Hospital. On admission physical examination showed epigastric tenderness and spasm. The liver edge was palpable 2 cm. below the right costal margin. In the right hypochondrium a round, smooth, tender mass was palpable. The diagnosis of subacute perforation of the stomach was made. At operation acute pancreatic necrosis was found to be the cause of the trouble. The gall-bladder was normal.

Six months after the operation a large slough of degenerated pancreatic tissue was discharged through the fistula which had persisted after laparotomy. Since the time of operation up to the present date (June 15, 1922) the fistula has remained open. Since that time the patient had few subjective symptoms, except when full drainage from the fistula was interrupted. A few weeks prior to the present examination he was told there was sugar in his urine.

On admission, June 10, 1922, the patient complained of no subjective symptoms. The physical examination showed the fistula, and the liver edge was palpable 2 cm. below the right costal margin. The patient was 25 pounds under weight.

The usual clinical examinations of the blood were negative. Blood sugar was 0.2 per cent. Sugar tolerance test showed extremely high figures. The urine was negative (patient sugar-free on diet). The stools showed an excess of fat. The duodenal contents contained an excess of bile pigments, but showed no enzyme action.

CASE 14.—I. G. Female, aged 38. W. S. 247759. Admitted to the Massachusetts General Hospital February 1, 1922, and discharged April 5, 1922.

Diagnosis: Acute hemorrhagic pancreatitis. Acute cholecystitis.

Past medical history essentially negative.

Present Illness began three days prior to admission to the hospital, with sudden, moderately severe, colicky pain in the dorso-lumbar region, which soon spread over the entire abdomen. This pain was present on admission to the hospital. Although nausea had been constantly present, vomiting had occurred but once. There was anorexia and the bowels were obstinately constipated.

On physical examination the patient appeared to be in moderate discomfort. The abdomen was diffusely tender and spastic, especially in the midepigastrium. The temperature was 102, the pulse 110, and the respiration 24.

The blood count showed 10,000 white cells per c.mm. The Wassermann was negative. The urine was negative. Stools resulting from enema were very light brown in color and con-

tained microscopically increased amounts of fat droplets and fatty acid crystals. At the time of the first examination of duodenal contents for enzymatic activities (two weeks after operation) the stools were normal.

Operative note, February 1, 1922: Considerable free fluid in abdomen, at first straw colored and then blood tinged. Spots of fat necrosis were everywhere seen and were most numerous in the gastro-colic omentum near the pyloric end. The pancreas was inflamed and showed three hemorrhagic areas and an area of fat necrosis 5 cm. in diameter. The gall-bladder was small and its walls thickened, and it contained bile and purulent material.

CASE 15.—J. F. M. Male, aged 30. W. 1. 24-024. Admitted to the Massachusetts General Hospital February 15, 1922, and discharged March 9, 1922.

Diagnosis: Acute hemorrhagic pancreatitis.

Since the age of 14 the patient had taken a cathartic daily for constipation; also, during this period there had been recurring attacks of obstipation, associated with abdominal distention and discomfort. During the three months previous to admission the patient had gained 24 pounds in weight, the abdomen had gradually enlarged, and dyspnoea on strenuous exertion had developed.

Present illness: For the past week before admission to the hospital the patient had been more constipated than usual, with some abdominal distress. Two days ago he developed great discomfort in the abdomen, described as a marked sensation of pressure over the entire abdomen. The night before admission this feeling was so pronounced that he "thought he would die." There had been no colicky pains. He had been well morphinized by his physician. During the past two days there had been frequent vomiting, and not even water was retained; there had been no fecal vomiting. The bowels had not moved, but an enema on morning of day of admission produced a moderate result and flatus was passed that same evening. On the night of admission the patient felt comfortable.

On physical examination the patient appeared to be but slightly ill. Shifting dullness was demonstrable in the flanks, but no other abnormalities were noted in the abdomen. Temperature was 100.6, pulse 110, and respiration 22.

Hemoglobin was 80 per cent. White cells were 22,300 per c.mm., with 90 per cent. polymorphonuclears. The Wassermann reaction was negative. The vomitus was dark green in color and strongly acid. Stools examined on February 24, 26, 28 and March 2 showed an excess of fat, but were not pasty in appearance. The urine showed a slight trace of albumin, and for the first few days after admission a slight trace of sugar.

Operation, February 16, 1922. The abdominal cavity contained blood-tinged fluid. The

mesentery and omentum were spotted with areas of fat necrosis. The pancreas "had a soft necrotic feeling."

Patient was discharged to Out-Patient Department, March 9. Sugar tolerance test showed normal findings two weeks after the third specimen of duodenal contents was obtained for enzyme studies.

Duodenal contents were examined on March 7, 30, April 13 and July 17. When last seen the patient was in fairly good condition, and was gaining weight and strength.

CASE 17.—A. J. McC. **Preoperative Diagnosis:** Cancer of the head of the pancreas.

Postoperative Diagnosis: Chronic cholecystitis. Cholelithiasis; stone in common bile duct.

April 9, 1921. Patient was a housewife, 61 years of age. She had been jaundiced for one week, one and a half years ago. Fourteen months ago the left breast had been removed because of a nonmalignant growth about 10 cm. in diameter. Patient had first noticed jaundice four weeks before admission, associated with anorexia, nausea, epigastric distress and some loss in weight. On physical examination the patient showed deep jaundice; the liver edge was indefinitely felt 2 cm. below costal margin and the ascending colon was palpable.

Roentgen examination showed gastric hyperperistalsis and the second portion of the duodenum was moderately dilated.

From April 9th to 29th the jaundice remained unchanged. During that period the patient vomited all food taken up to April 22nd, after which date vomiting was less pronounced. The liver edge became palpable 4 cm. below the costal border. There developed a small, firm, nontender, egg-shaped mass, just below the edge of the liver in the midclavicular line.

Laboratory findings were essentially negative except for bile in the urine and fatty stools usual in obstructive jaundice.

On laparotomy, a large calculus was found in the ampulla of Vater. There was, however, no distention of the common bile duct, which did not contain bile. The gall-bladder was greatly distended, but the contained fluid was not bile colored.

May 13, 1922. The patient recovered and has been in good health to date.

CASE 18.—F. H. W. White female, aged 59. Med. No. 133791. Admitted to Massachusetts Homeopathic Hospital Nov. 26, 1921 and died Dec. 10, 1921.

Preoperative Diagnosis: Cancer of the head of the pancreas. **Postoperative Diagnosis:** Chronic cholecystitis, cholelithiasis.

The past medical history was essentially negative.

The present illness had begun four weeks prior to admission to the hospital. The earliest symptoms had been those of moderately severe dyspepsia, followed in a few days with jaundice

of the skin and sclerae. There had been no abdominal pain.

On physical examination the patient was seen to be deeply jaundiced. Her mentality was considerably dulled. The liver edge was palpable 3 cm. below the right costal margin. Its edge was rounded and its surface smooth.

The usual clinical examinations of the blood, including the Wassermann reaction, were negative. The urine and stools were those usual in obstructive jaundice.

At laparotomy a stone obstructing the common duct and located proximal to the ampulla of Vater was found.

CASE 21.—A. C. Italian male, aged 58. E. M. 249521. Admitted to Massachusetts General Hospital May 5, 1922, and discharged June 1, 1922.

Diagnosis: Chronic hepatitis. Chronic cholecystitis. Diabetes mellitus.

Past medical history was essentially negative.

Sixteen, fourteen, thirteen and twelve years prior to admission to the Massachusetts General Hospital the patient had had attacks of severe epigastric pain, associated with jaundice. Thirteen years prior to admission the gall-bladder region had been explored at laparotomy. Many adhesions were found about the gall-bladder, but no gallstones. The present attack was similar to those occurring in the past; and together with those occurring in the past was associated with a moderate degree of diarrhoea. During the three months prior to admission there had been polyuria and polydipsia; glycosuria had been demonstrated recently in the Out Patient Department of the Hospital.

On physical examination at the time of admission the patient's sclerae were jaundiced and he was considerably under weight. The edge of the liver was palpable at the right costal margin, while the spleen reached 4 cm. below the left costal margin.

Hemoglobin was 65 per cent., white blood cells 6,500 and red cells 5,544,000 per c.mm. Blood sugar was 0.2 per cent. The urine showed no bile; the stools did not show abnormal amounts of fat.

On May 10th, 1922, duodenal contents collected for enzyme studies contained much bile. At this time 60 c.c. of 33 per cent. magnesium sulphate were instilled into the duodenum. Duodenal contents were again collected on May 15, and contained much bile. At the time of the second collection the patient was not jaundiced, although the blood plasma contained an excess of bile pigment.

CASE 22.—M. N. Female, aged 52. W. S. 248135. Admitted to Massachusetts General Hospital February 21, 1922, and discharged April 5, 1922.

Diagnosis: Cholelithiasis. Chronic cholecystitis.

Complaint: Epigastric pain and jaundice of four months' duration.

Past medical history was essentially negative.

Present illness. Fourteen years prior to admission the patient had been "yellow sick" for six weeks. The present illness began four months before admission. During this period there had been attacks of severe pain, beginning in the right upper abdominal quadrant and radiating around the left costal margin to the dorso-lumbar region of the back. With the onset jaundice had developed and still persisted on admission to the hospital, although it had varied in its intensity. Anorexia was present and the patient had lost 17 pounds in weight.

On physical examination jaundice of the skin and sclerae was noted. Otherwise the physical examination was essentially negative.

X-ray studies of the gastro-intestinal tract were negative.

Hemoglobin was 80 per cent, and white blood cells 10,000 per c.mm. The Wassermann on the blood serum was negative.

Gastric analysis showed no free HCl and total acidity of 14. On February 26 the bile pigment in the duodenal contents was about one-third the normal amount and enzymatic activities were low. On February 28, the pancreatic enzyme action was normal. A solution of 33 per cent. magnesium sulphate had been instilled into the duodenum following the first examination.

Operation March 7, 1922. Gallstones were removed from the common duct, which was dilated. The gall-bladder was thickened and bound down by adhesions.

CASE 23.—A. J. B. Med. No. 17493. Admitted to Peter Bent Brigham Hospital December 31, 1921, and discharged January 23, 1922.

Diagnosis: Gallstones. Questionable syphilis.

Patient is a well-developed Hebrew of 47, who gives a definite history of syphilis, including primary and secondaries of 18 years ago, and also of central nervous system lues ten years ago. Adequate treatment had been taken; and on admission to the hospital the Wassermann on the blood serum was negative. Fourteen years ago the patient had been jaundiced for four days. The present attack of jaundice began six weeks prior to admission to the hospital and had progressively deepened. Associated symptoms were nausea one hour after meals and girdle pains of greatest intensity in the dorso-lumbar region, radiating to the shoulder blades.

On physical examination icterus was deep. The liver edge was 5 cm. below the costal border. The liver surface was smooth and the edge soft.

Röntgen examination showed the duodenum to be persistently flattened on its superior surface, and on this surface its outline was half-moon shaped. This finding suggested an extra-duodenal lesion. The large bowel was not unusual by barium enema.

The usual laboratory examinations of the blood and gastric contents were negative. The

urine and stools showed the findings usual in jaundice. Wassermann reaction on blood serum was negative.

Duodenal lavage, 33% $MgSO_4$, 50 c.c., on January 4 and 5; 400 c.c. and 320 c.c. of colorless fluid obtained. January 11, after a meal of 40 c.c. of 20% cream mixed with 10 gms. $BaSO_4$, the duodenal contents were light yellow in color (due to bile).

January 23, discharged; less jaundiced than on admission and in good general condition.

CASE 24.—M. W. Female, aged 53. W. S. 247363. Admitted to the Massachusetts General Hospital, January 12, 1922, and discharged February 11, 1922.

Diagnosis: Cholelithiasis. Chronic cholecystitis.

The past medical history was essentially negative.

Present Illness: Two years before admission to the hospital there had been an attack characterized by dull epigastric pain, some vomiting and much weakness. This attack lasted one week. Eight months before admission the patient had been studied on the Surgical Service of the Peter Bent Brigham Hospital. At that time she had been jaundiced for six weeks and complained of much dull pain in the right side of the epigastrium. The jaundice remained for nearly three months and then gradually disappeared. During the next five months the patient was free from symptoms, except for transitory, mild epigastric pain. The patient then became jaundiced again and entered the Massachusetts General Hospital.

Physical examination showed the patient to be somewhat emaciated. The skin and sclerae were jaundiced. The liver edge was palpable 3 cm. below the right costal border.

Hemoglobin was 75 per cent, and white blood cells 11,200 per c.mm. The urine contained very little bile and occasionally some sugar. The stools were light brown in color and microscopically showed large amounts of fatty acids (patient on a low fat diet). The duodenal contents contained much bile after the use of magnesium sulphate.

At operation the gall-bladder contained many stones and a stone was found in ampulla of Vater. The gall-bladder and bile ducts were markedly thickened, and the pancreas was hard and apparently fibrosed.

CASE 25.—N. M. Female, aged 53. W. S. 248020. Admitted to the Massachusetts General Hospital February 15, 1922, and discharged April 13, 1922.

Diagnosis: Cholelithiasis. Chronic cholecystitis. Chronic cholangitis.

Complaint: Attacks of pain under right costal margin, of seven to eight months duration. Past medical history was essentially negative.

Present Illness: During the seven or eight months previous to admission there had been

attacks of pain in the gall-bladder region. The pain was severe at times and radiated to the interscapular region of the back. The attacks usually occurred at night and lasted several hours. At times the stools had been white and the urine very dark in color. The right upper quadrant of the abdomen had been tender. For the past week the bowels had been constipated.

On physical examination icterus of the skin and sclerae was present. The patient was totally deaf. A mass about 3 cm. in diameter was palpable in the right epigastrium, with associated spasm and tenderness.

Hemoglobin was 95%. White blood cells were 18,800 per c.mm., with 82 per cent, polymorphs. The urine and stools were of the character usually found in obstructive jaundice.

Duodenal tube introduced on March 16th. After instillation of 50 c.c. of 33 per cent, magnesium sulphate the fluid obtained was colorless. Following this the cream meal was given and duodenal contents obtained for enzymatic studies.

Operation, February 23, 1922. The gall-bladder was imbedded in a mass of inflammatory tissue and was packed with gallstones. It was impossible to explore the common bile duct or region of the pancreas on account of the extent of the inflammatory process.

The patient was discharged nearly two months after the operation. During this time complete obstruction to the flow of bile into the duodenum remained and the jaundice was unchanged.

CASE 26.—A. F. Male, aged 61. W. S. 428283. Admitted to Massachusetts General Hospital March 1, 1922, and died March 9, 1922.

Diagnosis: Acute cholecystitis. Pylephlebitis.

Six years prior to admission the patient was sent to Westboro because of "nervous breakdown." During the past five years there had been occasional attacks of dyspepsia characterized by "sour stomach," belching and epigastric distress after meals.

Present Illness: Six days ago while at work patient was seized with a sharp, knife-like pain below the ensiform, rather spasmodic, but persisting without definite remission until the present. He was able to finish his day's work, but went to bed that evening and stayed there. The pain became duller, spread downwards and backwards over the abdomen and into the flanks, and was fairly constant. It was made worse by exertion and was not affected by vomiting or by movements of the bowels. He vomited twice that day, and vomited practically everything eaten since then, but never blood. The vomitus always tasted very sour. He obtained several loose movements a day by the use of salts. He felt feverish several times and sweat a great deal. His urine had been scanty and high colored.

On physical examination the skin was flushed

and moist. There was some dyspnea, although no cardiac lesion was demonstrable. Percussion demonstrated shifting dullness in the flanks. There was moderate tenderness along the right costal margin and in the mid-epigastrium.

The white blood count was 14,000 and 15,000 per c.mm. Wassermann was negative. Urine and stools were negative. On March 7 the duodenal contents contained a large excess of bile pigments and the sediment indicated inflammation of the entire biliary tract.

Operation, March 9, 1922. Distended and thickened gall-bladder, without stones, was found. It contained dark, tarry bile and was evidently infected.

CASE 28.—D. B. Male, aged 50. W. M. 247541. Admitted to Massachusetts General Hospital January 20, 1922.

Diagnosis: Obstructive jaundice. Carcinoma of the gall-bladder, bile ducts and liver.

Past medical history was essentially negative.

Present illness: Eight weeks before admission patient had an upper respiratory infection, followed one week later by jaundice. The jaundice did not clear up under treatment, and after five weeks' severe pruritus became an additional symptom. He went to a hospital, but showed no improvement after three weeks' care. On admission to the Massachusetts General Hospital the presenting symptoms were deep jaundice, pruritus, anorexia, fatigue and insomnia. There had been no abdominal pain at any time. Urine had been dark and stools clay colored since onset. There had been no fever or chills. About thirty-five pounds had been lost in two months.

Physical examination showed a well-developed, somewhat emaciated man, deeply jaundiced. The skin was deep greenish yellow and showed many abrasions from scratching. Liver dullness reached up to the 4th interspace and the liver edge was felt 1 cm. below the right costal margin. In the left epigastrium a small, round, movable mass was felt just under liver edge, moving with respiration; this was probably the gall-bladder.

X-ray studies of the gall-bladder and gastro-intestinal tract were negative.

Red blood cells were 3,984,000 per c.mm. and white cells 10,000 to 14,000 per c.mm. The differential count was normal. The Wassermann reaction on the blood serum was negative. The gastric analysis showed free HCl 29 and total acidity 60. Duodenal contents showed no bile after food or after the instillation of magnesium sulphate into the duodenum. The urine and stools were of the character usual in obstructive jaundice. Operation was refused.

CONGENITAL OBSTRUCTION OF THE BILE DUCTS AND CONGENITAL BILIARY CIRRHOSIS OF THE LIVER.*

BY J. KEITH GORDON, M.D., BOSTON.

THE incidence of cases reported in the literature as congenital biliary cirrhosis of the liver *per se* is a comparatively low one. In most instances the condition has been associated with an obliteration of the main bile passages, with the result that the cirrhotic feature itself has been regarded as a secondary and perhaps less important process.

In 1911 Howard and Wolbach¹ reviewed the literature and succeeded in collecting seventy-six cases of congenital obliteration of the bile ducts, including a case of their own, and exclusive of those directly associated with syphilis. With the exception of nine of the earlier cases, a microscopical examination of the tissues had been a routine procedure and the constant accompanying finding had been a cirrhosis of the liver, the biliary type predominating. They divided the cases they encountered into the following groups:

- I. Obstruction of the hepatic and common ducts: gall-bladder and cystic duct patent.
- II. Obliteration of the gall-bladder and cystic duct; hepatic and common ducts patent.
- III. Obliteration of the cystic and hepatic ducts; common duct patent.
- IV. Obliteration at a variable point below the junction of the cystic and hepatic ducts.

The majority of these cases fell into Group III.

J. B. Holmes² in 1916 reported a case and made an exhaustive review of the literature on the subject. In addition to his own he cited 108 authentic cases of congenital obliteration of the bile ducts and by means of eighty excellent drawings representing the conditions as he found them showed diagrammatically at what point or points in the extra-hepatic biliary apparatus there might be an anatomical cause for interference with function. In reality these diagrams but represent in detail the broad classification of Howard and Wolbach with the addition of two conditions evidently overlooked by the latter writers, namely, the obliteration of the extra-hepatic biliary apparatus in its entirety, and a complete absence of any part or parts thereof. Holmes' lucid and concise diagrams are of particular interest to the surgeon, to whom he thus demonstrates how operative

* From the Department of Pathology, Harvard Medical School and Pathological Laboratory of the Children's Hospital, Boston.

procedures in effecting a passage of bile to the duodenum would be possible in a fair percentage of cases.

In a series of 1086 consecutive autopsies at the Children's and Infants' Hospitals, Boston, there have occurred but four cases of congenital obliteration of the bile ducts. Briefly, the case histories and pathological findings of these cases are as follows:

Baby H. P., female, aged 5 months, was admitted to the Infants' Hospital on July 30, 1915, with the following history: The father and mother were living and well. There was one other child living and well. There were no deaths, stillbirths, miscarriages, or history of tuberculosis in the family. The patient was a full-term baby with normal delivery, and had always been breast-fed. He vomited constantly since birth. There had been no jaundice during the first two weeks, since which time jaundice had developed and had been progressive. Coincident with this the stools had been clay-colored and the urine dark. The baby had lost weight during the month prior to admission.

Examination of the patient revealed nothing abnormal except a generalized icterus with clay-colored stools and highly colored urine. Seven days after admission the liver and spleen became palpable. Bronchopneumonia developed and the child died on the 10th day after admission. An autopsy was performed thirteen hours after death and the following are the main features abstracted from the protocol: General icterus was present. The liver weighed 320 grams and was firm in consistency. Its surface was very irregular, having a fine hob-nailed appearance. The color of the peritoneal surface was a dark greenish purple. The cut surface showed a fine hob-nailed appearance similar to that seen on the peritoneal surface. Between the liver lobules there was a fibrosis which in the gross appeared as fine white lines. The gall-bladder had no cavity and presented as a mass of fibrous tissue. The hepatic, cystic, and common ducts were all obliterated, forming fibrous cords without any lumen. The papilla of Vater was not visible.

The spleen weighed 70 grams. There were patches of consolidation in both lungs.

Microscopically the liver showed a fibrous connective tissue increase, confined practically to the portal areas and about the lobules. The connective tissue did not extend extensively into the lobules, nor was it increased around the central veins. The bile ducts in the portal spaces were increased in number, but not dilated. Some of the larger ones contained bile casts. The capillaries also were increased in number. In some areas there was a rather extensive vacuolization of the liver cells.

Thus, in recapitulation, a female infant developed jaundice two weeks after birth. She

was admitted to hospital at the age of five months, was deeply jaundiced, and died ten days after admission. An autopsy revealed complete obliteration of the gall-bladder, and cystic, hepatic and common ducts. Microscopically the liver showed a biliary cirrhosis.

A case of this kind might constitute a possible Group V.

A second case, reported by Dunn³ in 1916, showed no gall-bladder or extra-hepatic duct pathology, but microscopically the liver gave evidence of a mixed type of cirrhosis, together with an extreme degree of degeneration of the liver cells.

This might constitute a seventh group.

A third case is as follows:

Baby F. B., female, aged 7 days, was admitted to the Infants' Hospital on May 10, 1919. The following history was obtained from the parents: The father, mother, and one other child were alive and well. There was no history of miscarriages. In April of the previous year a child had been born which became markedly jaundiced on the second day after birth and died three days later. The patient was a full-term baby, apparently normal at birth, but became jaundiced on the second day. The jaundice increased each day. The stools were white, and the urine highly colored. On examination the liver was palpated 3 cm. below the costal border and the spleen was also palpable. Except for a deep icteroid tinge to the skin, sclerae, and buccal mucosa, there were no abnormal physical signs. The child died soon after admission to hospital. An autopsy was performed, and the following are the main features abstracted from the protocol:

There was generalized icterus. The liver extended 3 cm. below the right costal border and 3 cm. below the ensiform. It weighed 175 grams and was moderately enlarged. Its surface was smooth and of a dusky red color. On section the lobular markings were indistinct and the cut surface had a yellowish cast to it. The hepatic veins contained fluid blood. The gall-bladder was narrow and shrunken, though containing about 2 c.c. of black mucilaginous bile. It was possible to pass a probe through the cystic duct in its entire length. The hepatic duct had a lumen too narrow for the smallest probe available. The common duct was represented by a narrow fibrous cord in which no lumen could be demonstrated either by expression of bile, passage of probe, or dissection. The other organs were not remarkable in the gross.

Microscopically the normal architecture of the liver was preserved, but there was moderate congestion and oedema separating the columns. There were acute degenerative changes in the liver cells in the mid and peripheral zones, with necrosis and invasion by many polymorphonuclear leucocytes. Inspissation of black bile in

the bile capillaries was prominent. Bile had also escaped from the bile capillaries and lodged outside the liver cells, where it was taken up in quantity by endothelial phagocytes. There was a slight increase in fibrous tissue about the portal areas, and this was infiltrated with lymphoid cells, eosinophiles, and a variable number of polymorphonuclears. The bile ducts were not dilated. Many contained plugs of brownish black bile and were lined by rather low epithelium. A few showed proliferation. There was no fat in the liver cells.

To sum up: a female infant developed jaundice on the day of birth. This condition increased until death occurred on the seventh day. On autopsy an obliteration of the common duct was found. The hepatic, cystic ducts and gall-bladder were patent. Microscopically the liver showed focal necroses and a mild type of biliary cirrhosis. The case corresponds with Group IV, according to Howard and Wolbach's classification.

The case history and pathological findings of a fourth case, which corresponds very closely to that of Dunn's, are as follows:

Baby S. W.,* aged 7 days, female, was admitted to the hospital in the service of Dr. Stone, on December 17th, 1921. The patient's father, mother and three brothers, aged 7, 12, and 15 years, were all living and well. There was no history of tuberculosis, syphilis, insanity, or hemophilia in the family, and the mother denied any miscarriages or stillbirths.

The patient was a full-term baby, delivered instrumentally, and had not been exposed to any of the acute exanthemata.

At birth the patient was noticeably jaundiced. She had been breast-fed until the day before admission, when she refused to nurse, since which time she had been fed breast milk with a bottle. The patient weighed 9 pounds, 9 ounces at birth. The stools had contained considerable mucus and at times had been gray. During the two days prior to admission, the stools had been black and had contained mucus. The urine had been highly colored since birth. On the day before admission some reddish-blue spots had been noticed on the body which were increasing in size.

Examination revealed a well developed and well nourished female infant weighing 8 pounds and 6 ounces. The skin, even by artificial light, was seen to be markedly jaundiced. There were ecchymoses over the left cheek, both elbows, right knee, and right breast. In the latter location the ecchymotic patch was two inches in diameter. The head was symmetrically shaped without points of tenderness. The sclerae, cornea and conjunctivae were of a yellow color. The pupils reacted to light and accommodation and the extra-ocular movements were well per-

formed. There was no discharge from the ears and no mastoid tenderness. There was no deformity of nor discharge from the nose.

The tongue was dry and along its margin were seen small discrete hemorrhagic areas. The pharyngeal mucous membrane was of normal color and the tonsils showed no evidence of previous or present involvement.

The heart and lungs were negative.

The edge of the liver was felt and percussed two fingers' breadth below the costal margin. Otherwise the abdomen was negative.

The nervous system, skeletal system and glandular system were all negative, and the genitalia and anus were normal.

An admitting diagnosis of congenital obliteration of the bile ducts was made.

On admission 25 c.c. of the father's blood was injected into the patient's buttock.

On December 19th, two days later, the patient had a spontaneous hemorrhage from the umbilical cord, which was clamped and tied after the loss of about one ounce of blood. Two hours later without warning the patient suddenly died.

An autopsy, which was performed five hours after death, revealed the following:

The body was that of a well developed and well nourished white female infant 46 cm. in length. The entire skin, sclerae, conjunctivae and buccal mucosa were of a most pronounced buff orange color. There were patches of ecchymosis varying in diameter from 1.5 to 6 cm. beneath the skin over both elbows, right mastoid region, dorsal surface of the hands, mesial surface of the left leg in its upper third, right patellar region, left internal malleolus, and left sub-scapular region. The umbilicus was about 1 cm. in length and there was blood clot and small granulations over its distal extremity. Rigor mortis was present but incomplete. There was no post-mortem lividity present. The pupils were equal and measured 4 m.m. in diameter.

There was an absence of free fluid and adhesions in the peritoneal cavity, and the lesser peritoneal cavity was free. The peritoneal surfaces were all moist and glistening, and the organs were all in normal position. The liver extended 4 cm. below the costal border in the right mid-clavicular line, 3 cm. below the costal border in the left mid-clavicular line, and 3 cm. below the ensiform cartilage. The foramen of Winslow was patent, there were no tumor masses or enlarged glands pressing upon the hepatic ducts and vessels, and the latter could be readily recognized and identified *in situ*. The diaphragm extended to the level of the fourth rib on the right side and to the level of the fifth rib on the left. The appendix measured 3 cm. in length and was free. There was no enlargement of the mesenteric lymph nodes. The thymus weighed 17 grams and was re-

*From the Surgical Service of the Children's Hospital, Boston.

markable only in that it was of a yellowish golden color. There were no enlarged mediastinal lymph nodes. The lungs were collapsed. There was no fluid nor adhesions in the pleural cavities. The pleurae were of a yellowish golden color.

There were no adhesions and but a few c.c. of clear yellowish fluid in the pericardial cavity. The pericardium was of a yellowish golden color.

The heart weighed 33 grams. The epicardium was smooth and glistening and of a yellowish golden color. There was no increase in the amount of epicardial fat. The myocardium was of a pinkish red color tinged with yellow and firm in consistency. The endocardium was smooth and glistening, and of a yellowish golden color except for a small area on the line of closure of the anterior segment of the mitral valve, where there were three minute scattered dark red raised smooth and glistening points, which were evidently foetal vascular remains in the endocardium. Otherwise the valves were normal. The foramen ovale was closed and the coronary orifices were patent.

Measurements: T.V. 4 cm.; P.V. 2 cm.; M.V. 3 cm.; A.V. 2.2 cm.; L.V. 6 mm.; R.V. 3 mm.

The combined weight of the lungs was 45 grams. The right lung was smooth and glistening externally and of a yellowish color. It was crepitant throughout. The cut surface was of a yellowish salmon pink color and there were no gross signs of consolidation. The left lung resembled its fellow on the opposite side except that at the apex of the lower lobe there were a few small scattered reddish ecchymoses beneath the visceral pleura.

The spleen weighed 15 grams. Externally it was of a deep magenta color and the capsule was slightly wrinkled. In consistency it was firm. On section it cut with increased resistance and seemed somewhat rubber-like. The cut surface was of a dark brownish red color and the lymph follicles were not visible. The pulp did not scrape.

The entire gastro-intestinal tract was of a yellowish golden color. The intestinal contents were of a grayish color streaked with black. Otherwise it was not remarkable.

The pancreas was of a yellowish golden color, but otherwise not remarkable. The pancreatic duct of Wirsung was patent.

The liver weighed 280 grams. Externally it was smooth and glistening throughout and of a muddy brown color. The shape, relative size of the lobes, and position of the fissures were normal. In consistency it was firm. On section the organ cut with slightly increased resistance and the cut surface was of a muddy brown color with small irregularly shaped patches of a lighter brown scattered throughout. The gall bladder was collapsed. It was possible to pass a probe from the papilla of

Vater both into the gall-bladder and to the liver, thus proving that the common, hepatic, and cystic ducts were patent. There was no foreign body present. When normal saline was injected through a cannula into the common bile duct it was seen that the fluid emerged from the larger intra-hepatic ducts on the cut surface of the liver, thus intimating that the main bile tributaries were patent.

The combined weight of the kidneys was 33 grams. The foetal lobulations of the left kidney were well marked. Its capsule stripped easily, leaving a smooth and glistening muddy brown surface. On section the cortex was of a muddy brown color and measured about 4 mm. throughout, bearing a normal ratio to the thickness of the medulla. The latter portion was of a yellowish red color. The pelvis and ureter were of a yellowish golden color, but were otherwise not remarkable. The right kidney resembled its fellow on the opposite side in every respect.

The adrenals were somewhat enlarged. On section the left adrenal appeared normal, but in the medullary portion of the right adrenal there was considerable dark red clotted blood.

The genitalia were negative.

The aorta was of a yellowish color, but otherwise negative.

The dura surrounding the spinal cord was of a light golden brown color, but the cord itself appeared normal.

An examination of the head was not permitted.

PATHOLOGICAL HISTOLOGY.

Liver: Microscopically this organ showed a slight increase in the amount of fibrous tissue surrounding the portal areas. It varied slightly in amount in different locations, but not a single portal area had escaped the process. Accompanying this fibrosis, there was a cellular reaction which consisted of relatively large numbers of eosinophiles, together with some mononuclear wandering cells, large and small lymphocytes, and a few polymorphs. This process did not extend in between the liver cells or columns, but remained more or less localized and appeared to produce a crowding of the neighboring liver cells rather than their destruction. The appearance of the bile ducts varied in different fields. Some were definitely patent, with empty gaping lumina; others appeared to be compressed, yet their lumina were patent and empty; while a great many were occluded by casts of inspissated bile. In not one instance, however, was there a flattening of the lining epithelium of the ducts, nor could any actually obliterated ducts be found. Serial sections through the liver showed that though the smaller bile twigs pursued a somewhat tortuous course they finally established a connection with the liver columns. About

some of the central veins there was a fibrous connective tissue increase, accompanied by an occasional eosinophile and lymphocyte, but to a much less marked degree than that seen at the periphery of the lobules.

There was considerable phagocytosis of bile by the endothelial cells and also by some mononuclear phagocytes lying within the sinusoids.

The liver cells themselves showed a marked stippling of their cytoplasm, with basic staining granules of irregular size and shape. Sections stained with Best's carmine stain showed that this latter phenomenon was due to the presence of an excessive amount of glycogen within the cells.

Pancreas: There was an increase in the amount of interstitial tissue separating the acini which amounted to a diffuse cirrhosis of a mild type. This fibrous connective tissue was accompanied by an occasional eosinophile and lymphocyte. The majority of the smaller ducts had their lumina occluded by acid-staining homogeneous colloid-like casts of what was evidently pancreatic secretion, and some of these gave evidence of being distended by the fact that their lining epithelium was flattened. The larger ducts were normal and the cells of the acini and islands were likewise.

Kidneys: The collecting tubules were filled with brownish colloid-like casts, but with the exception of this and a diffuse staining of the tubular cells with bile the organs were normal.

Adrenals: There was a marked degree of hemorrhage into the medullary portion of the right adrenal.

Splinal Cord: This was essentially normal, but remarkable in that it was the only tissue of the body examined which showed no evidence of icterus.

Sections stained by Wolbach's modification of Giemsa stain in order to demonstrate microorganisms in the tissues showed no direct evidence of infection.

Thus, to summarize, a female infant was markedly jaundiced at birth. On the 7th day, she was admitted to hospital and died very suddenly two days later. An autopsy revealed generalized icterus and patulous extra-hepatic duct and gall-bladder. Microscopically the liver showed a biliary cirrhosis and the pancreas a fibrosis.

There are then, with minor variations, seven anatomical possibilities which embrace the condition known as congenital obliteration of the bile ducts, and they are as follows:

I. Obstruction of the hepatic and common ducts; gall-bladder and cystic ducts patent.

II. Obliteration of the gall-bladder and cystic duct; hepatic and common ducts patent.

III. Obliteration of the cystic and hepatic ducts; common duct patent.

IV. Obliteration at a variable point below the junction of the cystic and hepatic ducts.

V. Obliteration of the gall-bladder and cystic, hepatic, and common ducts.

VI. Complete absence of any part or parts of the extra-hepatic biliary apparatus.

VII. Obliteration of the intra-hepatic ducts with patulous gall-bladder and extra-hepatic ducts, *i.e.*, a biliary cirrhosis of the liver.

It can be seen that when the condition is such as exists in Groups II and IV, surgical procedures, if attempted, might be successful in producing a restoration of the normal mechanism. Reports in the literature of such cures are extremely rare, however, owing, perhaps, to the fact that a comparatively small percentage of all cases recorded fall into Groups II and IV, and that the majority were unsuitable for operation, that the accompanying cirrhosis was of such an extent and nature as to cause bile stasis of itself even after the obstruction in the extra-hepatic ducts had been relieved, and that operation was only performed as a last resort when the patient was in a moribund condition. Nevertheless, in view of the otherwise hopeless outlook, it can be reasonably stated that surgical interference is advisable in all cases wherein a positive diagnosis of congenital obliteration of the bile ducts has been made.

In regard to the pathogenesis of the condition, it is interesting to note that Thomson¹ in 1892 regarded the process as arising from a primary congenital malformation of the duct, which caused a catarrh and a complete blocking of the same. This in turn led to a damming back of the bile and a cirrhosis of the liver.

Rolleston,² writing in 1905, held that the cirrhosis was the primary condition, and that a cholangitis was produced which descended to the larger ducts and brought about an obliterating fibrosis. He supported his views with the arguments that although there was a constant cirrhosis accompanying obstruction of the bile ducts in infants, in adults cirrhosis of the liver did not accompany aseptic obstruction of the bile ducts, as in the case of carcinoma of the head of the pancreas; also, that the enlarged liver found in these cases resembled the hypertrophic cirrhosis of Hanot; that the spleen was generally found to be enlarged, a feature absent in uncomplicated biliary obstruction; and, finally, that in some instances several cases had been noted to occur in the same family. He still believes that "biliary obstruction *per se* does not constantly cause any form of cirrhosis; but with infection of the obstructed ducts pericholangitis may lead to hepatic fibrosis."³

Lavenson,⁴ in reporting a case of congenital obliteration of the bile ducts with cirrhosis of the liver, in 1908, made a survey of the literature and came to the following conclusions:

(1) That in the congenital condition, of which the two most prominent features are an obliteration of some portion of the bile ducts and a more or less extensive degree of cirrhosis of the liver, the obliteration of the ducts is the primary condition and the cirrhosis is a result of the ensuing biliary stasis.

(2) That the term "atresia of the bile ducts" better expresses the existing condition than "obliteration of the bile ducts." Laveson thus stands in direct opposition to the views of Rolleston, whose arguments he attacks by asking why the descending cholangitis is not found more often as a result of the Hanot's cirrhosis in adults, and why the obstruction in infants is most commonly in the hepatic portion of the ducts. This latter fact was not borne out by Howard and Wolbach's thorough analysis, however, as I have already mentioned. Laveson disregards the enlarged spleen that Rolleston mentions as not having any bearing on the subject, and claims that in a thorough search he could find in the literature but one case in which there was an occurrence of the same disease in one family, and that this had undoubtedly been syphilitic in origin. In support of the congenital malformation theory he shows how faulty union of the two rudimentary portions of the ducts is embryologically possible, and that in a few cases additional congenital defects were noted at autopsy.

For the reason that the rather intricate development of the liver and bile ducts allowed of infinite possibilities in the way of congenital malformation, Holmes, who made the last important contribution on the subject, concluded as follows: "Accumulating evidence tends to show that the condition is usually a developmental anomaly and not the result primarily of inflammatory processes." He believed that the cirrhosis in every instance was a result of the obstruction in the main ducts, and thus regarded Rolleston's theory as lacking in support.

None of the above writers make mention of a case similar to Dunn's nor to the one herein reported by myself, both of which lean towards the likelihood of a non-infectious agent being the etiological factor, and which likewise tend to favor the theory of a cirrhosis being primary to the obliteration of the ducts, for although in cases where congenital obliteration of the extra-hepatic ducts occurs there is a constant accompanying cirrhosis, the converse of the rule on the other hand does not hold true. In other words, congenital cirrhosis of the liver does occur without obliteration of the extra-hepatic ducts.

Doubtless the etiological factor may be either a pure congenital malformation or a pure inflammatory process, or possibly, as might often be the case, a congenital malformation with an inflammatory process grafted on. From the standpoint of treatment and prognosis the mat-

ter appears of little import. The fact that a biliary cirrhosis of the liver is constantly present would seem to be the most perplexing factor, for although it is highly probable that this type of cirrhosis is not a progressive one, it is also apparent that in some of its forms, as was found in the case reported above, it is incompatible with life.

To separate congenital biliary cirrhosis of the liver and congenital obliteration of the bile ducts as distinct pathological entities seems unnecessary, since their connection is such an intimate one and so apparent is it that they are the end-result of the same etiological factor or factors, whether found separately or combined. Since the cirrhosis is the constant feature it would almost appear that the term "congenital biliary cirrhosis of the liver" is a more logical appellation for this condition than that of "congenital obliteration of the bile ducts."

CONCLUSIONS.

1. That, from a review of the literature, a mild or severe degree of cirrhosis of the liver constantly accompanies congenital obliteration of the bile ducts.
2. That a congenital biliary cirrhosis of the liver can occur without congenital obliteration of the bile ducts, and is, therefore, not a result of the latter.
3. That in view of the otherwise hopeless outlook, surgical interference is advisable in all cases wherein a positive diagnosis of congenital obliteration of the bile ducts has been made.

THE PROBLEM OF THE TUBERCULOUS SUSPECT.

BY JOHN B. HAWES, 2ND, M.D., BOSTON.

I HAVE chosen this subject of the "tuberculous suspect" because I believe that it represents a weak point in our endeavors to diagnose tuberculosis in its early stages.

Patients suspected of having tuberculosis may be divided roughly into three classes, only one of which I shall consider here.

The first group comprises many ex-service men who are called, "Tb. suspects." Although they constitute a difficult and trying problem, it is not one which often directly concerns the general practitioner, but is almost entirely in

the hands of the Veterans' Bureau or the Public Health Service.

The second group consists of those patients whom we all are constantly meeting in our private practice. This group is a large one or a small one, according to the diligence and skill of the physician and the impression he is able to make upon his patient as to the seriousness of his case. This group, likewise, I shall not consider here.

The third group to which I would call your attention consists of those patients,—men, women and children,—who attend our out-patient departments and dispensaries and in whom a provisional diagnosis of tuberculosis is made. It is a comparatively small and fortunate few who are given a definite diagnosis on the first visit. I have always maintained that the man who came in to an out-patient department and whose sputum was at once found to be positive to tuberculosis or who had a large hemorrhage while at the clinic might well be considered fortunate, simply because in his case the diagnosis was at once established and adequate treatment instituted. There are many, however,—the great majority indeed,—in whom the diagnosis is not so clear and who are, therefore, asked to return for x-ray examination, and with temperature and pulse records, sputum, etc. In such instances, the diagnosis usually put down on the patient's record is "Ph.?" These patients are always asked to return for further examination, but in far too many instances they do not return. The solution to this problem is not an easy one. The present situation as it exists in my own city is not satisfactory and I believe that the same situation exists elsewhere.

Early in the year 1921, when I became President of the Boston Tuberculosis Association, the first problem that I asked my Executive Committee to undertake was in regard to this point. I had often asked myself what became of the men, women, and children in whom I, for instance, at my clinic at the Massachusetts General Hospital, had made a provisional diagnosis of pulmonary tuberculosis and had asked to come back in a week for further study, but who never came back. What happened to them? Did they go to other dispensaries or to private doctors, or did they drift along until they reached the advanced stages of this disease? In far too many instances, the latter, I fear, was the true answer. At all events, I persuaded my Executive Committee to allow Miss Billings, the Executive Secretary of our Association, and myself to conduct a survey of the city with this point in view. A careful and detailed study was made of all patients in whom there had been a definite diagnosis or a provisional diagnosis of pulmonary tuberculosis at the six large out-patient departments and dispensaries of the city of Boston. The present condition of every one of those patients who came to these out-patient

departments from April, 1920, to April, 1921, was investigated.

The following was found to be the situation concerning the tuberculous suspect. Out of a total of 963 patients included in this study there were 415 in whom a provisional diagnosis of pulmonary tuberculosis had been made. From their histories it was evident that the great majority of these had been advised to return for further examination, but that in comparatively few instances had this advice been followed up by home visits, with the result that none of these 115 patients returned for a definite and final diagnosis to the out-patient department in which the provisional diagnosis had been given. There were 140 who afterwards visited some other institution or a private physician and were re-examined; 92, or 69 per cent., of whom were definitely diagnosed as having pulmonary tuberculosis and so reported. Even deducting this group, however, there remains a large number, 338, or 45 per cent. of the original 963 patients, who were strongly suspected of having tuberculosis, but who, so far as could be determined from the records, had never been re-examined or been given a definite diagnosis one way or the other. These patients were not known to the various social service departments of these institutions, nor had they ever been referred to any central office for purposes of record. It is clearly evident that these 338 patients who are now classified as unknown are in urgent need of home visiting and re-examination. This is a group of patients which ought not to exist, and which, if it must exist, should be reduced to the lowest possible figure. The following are two striking examples of what may happen, and indeed what has actually happened to some of these neglected provisional cases.

CASE A. This patient was given a provisional diagnosis of pulmonary tuberculosis in an out-patient department July 22, 1920. He was entirely lost track of until reported November 4, 1920, by a private physician. He died 15 days later, November 19, 1920.

CASE B. In this case a provisional diagnosis of pulmonary tuberculosis was made at one of the out-patient departments June 15, 1920. He was not heard from again until he was reported by another hospital, April 6, 1921, as having a chronic fibroid phthisis.

At a meeting that I asked Dr. F. X. Mahoney, Health Commissioner of the city of Boston, to call to consider this subject, representatives of the administrative staff and of the social service departments of the six institutions concerned were present. The question was raised as to whether the problem of the tuberculous suspect was really as big as my figures appeared to make it. There was a feeling that after all the majority of these suspects would turn out not

to have consumption. This is a pleasant and optimistic attitude, but, unfortunately, not a sound one. The mere fact that of the 140 suspects in whom the diagnosis was finally settled one way or the other, 69 per cent. turned out to have pulmonary tuberculosis, is sufficient to demonstrate that the problem is a real one.

What are we going to do about it? Various points are absolutely clear and certain to me. In the first place, my investigations demonstrate clearly the advantage of the "one-man" or "two-man" special clinic. The number of patients with a provisional diagnosis who never showed up again was infinitely greater at those general out-patient departments and dispensaries where everything medical is thrown into one large group with doctors in attendance, serving three or four months, than it is in the special clinics where lung cases only are seen, and where the same man or the same group of men are in attendance all the year round. At the clinic of Dr. E. O. Otis, for instance, where, at the Boston Dispensary, he has been in charge for years, there were few such provisional diagnoses, as was also the case, I am glad to say, at my own clinic at the Massachusetts General Hospital.

Next to this, and of no less importance in solving this problem, I would mention the social service departments. Every one of these "Th. suspects" should be automatically referred to the social service department for home investigation and, particularly, to see that the patient returns for further examination.

Finally, there should be some department or organization which should act as a clearing house to keep track of these patients. I would suggest, for instance, that as soon as such a provisional diagnosis is made, the patient's name and address be recorded at this central office just as positive cases now are. A record of such provisional cases coming from various dispensaries or hospitals in the city would give much more information concerning them than we now have and would prevent much duplication of effort and would permit of their being checked up should they go to another clinic.

The provisional diagnosis of tuberculosis is an unsatisfactory one and one which ought not to exist in large numbers. Some such system as I have outlined above, I believe, will help to reduce the number.

THE EDUCATION OF THE TRAINED NURSE.

BY CHANNING FROTHINGHAM, M.D., BOSTON.

At the present time there are many problems in regard to trained nurses which are unsettled. It is obvious from studying the different opinions set forth by those interested in the nursing profession that there is no unanimity of opinion in regard to the proper solution for various

ones of these problems. The question of the proper type of education for the trained nurse is one that has received considerable attention recently and presents possibly one of the most unsettled points in regard to the nursing profession.

In order to decide what is the proper education for the trained nurse it is important to have a clear conception of just what position the trained nurse should fill in the community. In this regard it is interesting to note the marked change in the possibilities for service which exist for the trained nurse of today in comparison with the trained nurse of only a few years ago, for the nursing profession is a relatively young profession.

At the start the nursing profession called for the training of young women so that they could assist in the care of sick people under the direct supervision of physicians. It was not expected that the trained nurse should assume much, if any, responsibility. At the present time there still exists as perhaps the most important function for the majority of trained nurses the care of the sick in the hospital or the home under the direct supervision of the attending physician. In this position it is not perhaps necessary for the trained nurse to assume much responsibility, nor need she have appreciable knowledge of disease and symptoms, provided the case is so situated that medical attention may always be within easy call.

As, however, medical attention is frequently not available on the instant in many hospitals and homes the nurse even in this capacity must assume more and more responsibility, and in order to do so properly it is advisable for her to have a fair knowledge of certain types of symptoms. Also numerous other opportunities for service exist for the trained nurse today in which she has to work more independently of the physician and has to assume considerably more responsibility. To do this properly the nurse must have more general knowledge of symptoms and disease than if she simply is caring for the sick under supervision. An example is the district nurse who goes out among the people in their homes and who may have to wait several days before a physician is able to visit the home, and who frequently has to decide as to the need for the physician's visit. Another example is the industrial nurse who works in manufacturing establishments and must in many cases assume the responsibility of deciding whether the particular case should see the physician, and also do a considerable amount of minor surgical work on her own initiative. Still another example is the Red Cross nurse who in responding to emergency calls must of necessity assume responsibility because, as she is working at a time of emergency, the probability is that sufficient medical supervision will not be available.

In the field of preventive medicine the trained nurse again has many opportunities for work in which she must assume a certain amount of responsibility and initiative, as, for example, the public health nurse, the dental hygiene nurse, the school nurse and the child welfare nurse. The names attached to the nurses are in themselves explanatory of the character of the work which they do, and no attempt in this short article will be made to go into the details of these various positions, or to enumerate all of them.

The trained nurse of today is frequently trained to be an anesthetist, and experience shows that a nurse trained in the giving of anesthesia with long experience can do it in a much more satisfactory manner than the young physician or medical student who has, perhaps, more theoretical knowledge in anesthesia, but has not had the practical experience. Many surgeons prefer a nurse for an operating assistant. The opportunity for work as laboratory assistants in research work is now open to the trained nurse. All of these positions should be more ably filled by the more broadly educated woman.

In addition to opportunities for work as described above which, although under the supervision of the medical profession, call for the assumption of responsibility and initiative on the part of the nurse, the trained nurse of today must be equipped to take the initiative in certain fields without any supervision, such as the position of teacher in training schools for nurses, and the position of educator of the public in matters of public health and hygiene. Furthermore, trained nurses have been and are successful administrators of hospitals. No attempt will be made to summarize all the possibilities that are open to the trained nurse along these lines at the present time. The ones mentioned above seem to make it clear that the trained nurse of today is called upon for many more different duties than the trained nurse of only a few years ago, and it seems likely that in the future the opportunities for the trained nurse for various types of service will continue to increase.

It is, therefore, quite evident that in educating young women in the nursing profession at the present time it is necessary to train them not only so that they will be equipped to care for sick people under direct supervision of the medical profession, but also so that they will be equipped to act as independent workers in various fields and as educators and leaders in certain positions.

The character of the education of the nurses in the training schools has also been undergoing a change during recent years. There is less drudgery in our better training schools. It is felt that the physical upkeep of the wards belongs to chorewomen and hired help rather than

to the pupils of the nursing profession. The hours for the pupils in the schools are shorter, so that there is more opportunity for general mental development. More general knowledge as preliminary to training is required of the pupil nurse, and more general education is given them during their course in many schools. The curriculum in the training schools in regard to general and special medical knowledge has been steadily enlarged. In fact, the question has been seriously considered whether the training school for nurses should be united with the university and at the end of a three or four years' course some degree similar to the Bachelor of Arts should be given.

Of course, all training schools throughout the country have not been able to advance their standards in the same degree, but the trend among the better schools has been in this direction. The result of this change in the education of the trained nurse has been that the nurse of today has a better general education, is better drilled on general health problems, and knows more about disease in addition to her training in the art of nursing than the trained nurse of a few years ago. Like other people who have put in considerable time on education, she expects more financial return per hour for her services than her less well-educated sisters.

Granting that the opportunities for service for the trained nurse of today are more varied than formerly, and also that the method of educating nurses has considerably changed and is still in a transition period, it is important to make a careful analysis of the situation in order to determine if the product of the training school of today is able to supply the needs of the community for the various nursing opportunities which exist. In regard to those opportunities for trained nurses which require leadership, initiative, assumption of responsibility and independent work, there can be no doubt but that the better educated the nurse is who undertakes this work the more successful she will be at it, other things being equal. Therefore the increase in the curriculum for the trained nurse in the better training schools seems to be a step in the right direction toward supplying nurses for these positions.

In regard to those opportunities for trained nurses which consist in care for the sick under supervision, it seems obvious that the better educated the nurse is who does this work the more successfully she will do it. In some quarters it has been suggested that the nurse with the more elaborate training does not do the actual nursing care so well, but it seems as though this must be simply individual variation rather than the result of too much extra knowledge. There seems to be no definite proof that education destroys one's ability in the nursing art, and, therefore, increased education for the nurse should give a better product for this

purpose also. From the viewpoint of the nurse's efficiency, therefore, it seems quite certain that the more highly educated product of our better training schools is better equipped than the nurses trained less well to care for all the needs of the community for trained nurses.

Unfortunately, however, on account of financial reasons, a large number of individuals feel unable to hire these highly educated nurses, who properly demand a larger financial return, and, therefore, today there is a need for nurses to care for those with limited financial resources who become ill. That the less broadly trained woman can care for the sick in a perfectly satisfactory manner under supervision has been amply proved by the past experience in the nursing profession, and, of course, a woman who has not spent so much time in preparation can hardly expect so large a financial return. If, therefore, this highly trained woman, although desirable, is not necessary for the proper care of the sick, and if she is without the reach of many, the trend in regard to the education of nurses is going to leave a need in the community unless some provision is made to supply individuals trained sufficiently to fill this gap.

Assuming for the moment that the preceding summary of the situation in regard to the opportunities for nurses, in regard to the education of nurses, and in regard to the needs of the community for nurses is correct, in what manner should our training schools organize in order to fulfil the needs of the times? The education of the pupil nurse should be kept at the present high plane that it is in our leading schools, with the idea of eventually placing the training school upon a university basis so that the work will lead toward an academic degree of some sort. With this foundation, our best trained nurses will be able to properly fill the numerous positions that are open to them. In addition, it is important that our training schools should turn out a class of women who are trained sufficiently to care for sick people under medical supervision, either in the home or in the hospital.

The details of how to accomplish this must be worked out by those who make a study of the nursing profession. Various possibilities suggest themselves. There might be a fundamental two-year course in nursing, at the completion of which some sort of a title is given to the individual. After the completion of this two years' course a woman can decide whether she will then go out into the world as a practical nurse, to care for the sick, or whether she will continue her studies along some special line, to prepare herself for some of the various fields, open to the trained nurse, which require more elaborate training. Probably at least another two years should be spent in this special preparation and study, and it would be at the end of this two years' work that some academic degree might be given.

Another possibility is the dividing up of the training schools into classes. Those training schools allied with universities and in the larger centers could give a longer course, with considerably more special instruction, with the object of preparing women for the positions that require initiative and leadership. Those schools with less equipment and situated away from these opportunities could offer shorter courses which would train women to care for sick people under supervision. The appropriate titles for these individuals and their relations to the various laws for registration of nurses would require thought and adjustment.

The main points which it has been attempted to emphasize in this short communication are: First, that the opportunities open to the trained nurse at the present time are such that it is important that her education should be extended rather than limited; and second, that although a nurse trained in this manner is probably better suited to care for a sick individual under supervision, she is educated more than is necessary for this work, and also commands a financial return which puts her out of the reach of a great number of people. Therefore it is important for those interested in supplying the community with individuals to care for the sick to provide some type of individual trained well enough to care for the sick person at a price which is within the reach of the great majority of the people.

THE STATES HAVE NOT MET THEIR OBLIGATIONS TO CHILDHOOD.

Notwithstanding the fact that nearly every State has put into its constitution the fundamental principle of the State's obligation in public education, there is not a State in the Union which has yet complied with these plain provisions and given to the boys and girls an equality of opportunity in education. Those who live in the country districts have not been provided facilities for obtaining an education which are in any respect the equal of the facilities which have generally been provided in all populous centers.

There is no other institution in America which has made so little progress in the last century as the rural school. Is this great, rich nation to tolerate this condition of affairs for another century? Or shall we comply with the plain demands which have been determined to be the American policy in education?—Thos. E. Finegan, State Superintendent of Public Instruction, Pennsylvania.

Where the State has bestowed education the man who accepts it must be content to accept it merely as a charity unless he returns it to the State in full in the shape of good citizenship.

Theodore Roosevelt.

THE MEETINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The American Association for the Advancement of Science will hold its annual meeting in Boston, beginning on Tuesday, December 26th. With an enrollment of over ten thousand members who represent a great variety of activities, the Association plays an important part in providing a much needed opportunity for the correlation of different branches of scientific work in America. The meeting is of especial interest to the medical profession, for the Association is the only large body in which medical men are brought into direct contact with scientific workers in other fields. The advantages of such an affiliation are well illustrated by the meeting to be held on the afternoon of Friday, December 29th, at which the Sections on Medical Sciences, Entomology, and Parasitology will unite for the discussion of border-line topics which are of interest to all three groups.

The Medical Sciences will be represented by Dr. R. P. Strong, of Harvard University, and Dr. A. B. Macallum, of McGill University, Montreal; Entomology will be represented by Dr. C. T. Brues, of the Bussey Institute, Harvard University, and Dr. L. O. Howard, of the United States Bureau of Entomology; Parasitology

will be represented by Dr. C. W. Stiles, of the United States Public Health Service, and Dr. C. A. Kofoid, of the University of California.

It is unusual that so distinguished a group of speakers is found on a single program, and physicians who are interested in the broader aspects of medicine will welcome the chance to hear authoritative statements from leaders in allied branches of science.

PASTEUR.

In the year 1815 Jean Joseph Pasteur, a soldier in the army of Napoleon, a knight of The Legion of Honor, and a farmer by trade, settled in the village of Dôle. On Friday, December 27, 1822, his son Louis was born, a child destined to plough unbroken fields of science and to extend the frontiers of exact knowledge to a degree seldom reached by man.

Louis Pasteur stands alone among the ranks of Humanity's benefactors; the position he attained, even during his lifetime, will be forever secure against the petty storm of hatred, envy, and ignorance that forever seeks to tear down the constructive work of those who are immeasurably greater than their opponents. Of Pasteur's battle in the Academy of Medicine, where the chemist who had solved the mysteries of Farh had continually to defend his ground against the enmity of a profession of which he was not a member—a profession that saw its traditional dogma and doctrine slipping away from it under the searching investigation of this man, many know. That he should have lived to see his great achievement acknowledged and recognized by the country he loved so well to serve, was a reward that falls to the lot of few.

Pasteur's childhood was that of an eager, though not a brilliant, student who sought by every means in his power to gain the knowledge that he felt was so necessary to his advancement, although, at that time, a professorship at Artois College seemed a reasonable goal for his ambitions. His course at the Ecole Normale, attendance at the Sorbonne Lectures, and the inspiration afforded by J. B. Dumas, later his master and lifelong friend, turned him into a chemist. At the age of twenty-six he revolutionized physical chemistry by discovering the constitution of racemic acid, and gained the lasting interest of Biot, the chemist, then seventy-four years of age. Biot at one time wrote to Pasteur's father, "It is the greatest pleasure that I can experience in my old age to see young men of talent working industriously and trying to progress in a scientific career by means of steady and persevering labour, and not by wretched intriguing."

Pasteur was in 1853 made a knight of The Legion of Honor. In 1856, as a result of the

troubles being experienced by the French brewers, he took up the study of fermentation. This was extended to wines in 1864. The year 1865 was epochal in Pasteur's career, for it was in this year that Dumas asked him to leave the laboratory and undertake the study of the epidemic that had been playing havoc with the silk worm industry since 1849. In 1869 the disease was conquered and immense revenue saved for France, although, the year before, Pasteur had suffered his first paralytic stroke.

The Prussian invasion soon checked investigation in France. Pasteur, unable on account of his paralysis to accompany his colleagues to the front, wrote bitterly, "I wish that France may fight to her last man, her last fortress. I wish that the war may be prolonged until the winter, when, the elements aiding us, all these vandals may perish of cold and distress. Every one of my future works will bear on its title page the words: 'Hatred to Prussia. Revenge! Revenge!'"

Pasteur in 1873 was elected to the Academy of Medicine by a majority of one vote, distrusted still by our profession although Lister had already in 1867 adopted Pasteur's theory of germs, and created antiseptis. It was not until 1877 that antiseptic methods were employed in Paris, despite Pasteur's unremitting advocacy of his cause.

Charbon, splenic fever, or anthrax, exceedingly common among sheep and cattle in France, gave up its mysteries before the experimental method, and successful prophylactic vaccination was discovered. Soon the first experiments on hydrophobia were begun; attenuation of the vision was found possible, and in 1885 Joseph Meister, the little Alsatian lad, became famous as the first human being to receive the Pasteur treatment.

Honor and recognition from all countries had been piling up upon him. He was fêted, welcomed, revered wherever he went. Medals were struck in his honor. Buildings, streets, villages were given his name. The most humble and the most ignorant looked upon him as their benefactor; his opponents became his disciples. Dr. Fleys, head physician of the Aurillac Hospital, said, in proposing a toast to Pasteur, "What the mechanism of the heavens owes to Newton, chemistry to Lavoisier, geology to Cuvier, general anatomy to Bichat, physiology to Claude Bernard, pathology and hygiene will owe to Pasteur. Unite with me, dear colleagues, and let us drink to the fame of the illustrious Pasteur, the precursor of the medicine of the future, a benefactor to humanity."

On November 14, 1888, the Pasteur Institute, built by public subscription among all classes, even little Joseph Meister contributing his share, was inaugurated. In a speech on this occasion M. Christophle remarked that "it might be said that in this public subscription all the virtues flow into unselfishness like riv-

ers into the sea." A jubilee in honor of Pasteur was held at the Sorbonne on his seventieth birthday, on which occasion he was presented with a medal bearing the inscription: "To Pasteur, on his seventieth birthday. France and Humanity grateful."

His work was about over, although his interest remained ever fresh. Diphtheria was being studied. Eleven years before, Klebs had discovered the bacillus, and now the antitoxin was discovered by Behring. The Pasteur Institute immediately began its manufacture, but the leader was failing. In 1894 he had an almost fatal attack of uremia from which he recovered, but the following year his weakness increased, he suffered from a series of paralytic strokes and on September 28, 1895, he died, having lived to see his work succeed and to know that it was good.

DR. BULKLEY'S RETIREMENT FROM THE NEW YORK SKIN AND CANCER HOSPITAL.

According to the *New York Times* the differences of opinion between Dr. L. Duncan Bulkley and the staff of the New York Skin and Cancer Hospital have led to the retirement of Dr. Bulkley. Dr. Bulkley has been outspoken in his opposition to the generally accepted views concerning cancer and has published in the daily papers articles denouncing the arguments in favor of surgery. One of the phrases used in writing on cancer work contained the following words: "a monument to humbuggery and sordid deception."

The hospital governors have issued the following statement:

"In view of the various communications to the lay press of this city by Dr. L. Duncan Bulkley, a member of the medical staff of the New York Skin and Cancer Hospital, the Board of Governors of the hospital feels constrained to make the following statement:

"The Board of Governors and the medical staff of the hospital are not in accord with the theories or the practice of Dr. Bulkley regarding the treatment of cancer. They believe that such practice as he advocates means the loss of valuable time for the patient and by so much diminishes the hope of relief which other methods, advocated and used by the ablest physicians and surgeons throughout the world, do give.

"It is the practice at the New York Skin and Cancer Hospital to use any and all the treatments which research and experience have demonstrated to be of value in such cases.

"In its own research laboratories it is ever seeking knowledge for the treatment, relief and cure of this most dreaded disease.

"Dr. Bulkley is by many years the oldest physician upon our medical staff, but he is no longer in active service at the hospital. The title 'Senior Physician' which he uses has never been authorized by the Board of Governors or by any by-laws of the hospital.

"For the Board of Governors,

"ELIJAH D. MURPHY, *President*."

Dr. Bulkley is 77 years old, has published books and articles on cancer setting forth his views. His ideas coincide with those expressed by a very small minority of the profession.

Often added years bring to physicians a generous appreciation of the work of those who have studied the same problems and whose reasoning and experience have led to diverse conclusions but occasionally one sees in the aged, inflexibility of mind and a bitterness of spirit wholly inconsistent with scientific ideals. Physicians above all others should exhibit fairness and even tolerance in the discussion of the problems of disease. Cancer only lends weapons to our opponents. It is not evidence of strength, and in this case rather of senility. We regret this exhibition which compelled the hospital governors to take drastic action.

THE ADVENT OF COUÉ.

The intended visit of Coué to this country will once more flood the press with tales of miraculous cures. Apparently the field of therapeutics is wide and free; anyone can enter the lists against the ills of the flesh, and provided his idea has an element of mystery and is untrammelled by the teachings of pathology, he will be sure of a following.

Certain of these fads are less dangerous than others. It is not unlikely, indeed, that those methods of which Couéism may be taken as a type, are beneficial rather than otherwise. There are many people suffering from imaginary ills, or from slight functional disturbances over which they are unnecessarily concerned. For such people, the tonic effect of a course of mental therapeutics is very advantageous. The very fact that numerous sufferers are joined in a common effort to secure health and happiness gives to such healers as Coué a power, through mass psychology, which transcends to a considerable degree the power which may be wielded along similar lines by any orthodox medical man working alone in his office.

Another group which might properly be brought under such a psychological influence, are those afflicted with incurable disease. Surely no one would grudge them the temporary alleviation of their sufferings by their newly aroused hope and courage.

The harmful effect of such a therapeutic revival appears when people suffering from a true

pathological condition are led by this will-o'-the-wisp to neglect the help offered by legitimate medicine.

MESSAGE OF DR. LINSLEY R. WILLIAMS TO MASSACHUSETTS.

With the opening of the Christmas Seal Sale in Massachusetts, Dr. Linsley R. Williams, president of the National Tuberculosis Association, sends this message to the citizens of the Commonwealth, outlining the situation in Massachusetts as viewed from the conning tower of the great national anti-tuberculosis association. Dr. Williams writes:

"Today Massachusetts is able to point to many fine accomplishments, including a splendid growth in State and local official health agencies. We rejoice with you in these accomplishments, especially in the great reduction in the number of deaths from tuberculosis," and he stated that against 5,291 deaths from this disease in 1911 the number in 1921 was only 3,853, despite the increase in population. While Massachusetts may emphasize its good work accomplished, those interested in public health work should be mindful of the fact that at the present time about 35,000 persons in the State have tuberculosis. The important matters in this connection are, first, that it is necessary to find these persons, and, secondly, a campaign of education must be carried on so that the people themselves may assist in stopping the further spread of this communicable disease. The Health Christmas Seal Sale has for one of its important reasons for being, its high value as an educator of the people.

"For this purpose the Massachusetts Tuberculosis League and its affiliated associations and committees throughout the State are asking for \$200,000 at Christmas time through the sale of Christmas Seals. As has often been said, within certain limits public health is purchasable. This applies to individual and community health. The tuberculosis movement in Massachusetts is fortunate in having behind it a body of volunteer workers who have important plans for 1923. Massachusetts has also within its borders the Framingham Tuberculosis and Public Health Demonstration carried on under the auspices of the National Tuberculosis Association. The Demonstration has aroused international interest in the effectiveness of its methods of finding and treating tuberculosis. Massachusetts, therefore, has the workers; and also has the knowledge based on years of experience of how to wage an effective warfare against tuberculosis. All that is needed is the funds with which to carry on the work during the coming year. I am sure that the people of Massachusetts will not fail to appreciate the importance of financing tuberculosis work adequately through the Christmas Seal Sale."

News Notes.

WORCESTER DISTRICT MEDICAL SOCIETY.—The regular meeting was held December 13th, at 4:15 P. M., in the G. A. R. Hall, Pearl street, Worcester. Program: Unilateral Fused Kidney, Dr. Walter D. Bieberbach, Worcester; Slides illustrating the value of Pyclography, Dr. Philip H. Cook, Worcester; The operability of Protastic Obstruction, Dr. J. Dellinger Barney, Boston. Discussion opened by Dr. O. D. Phelps, Worcester.

NOTE.—The committee appointed at the September meeting of the Society to consider the adoption for automobiles, of the A. M. A. emblem, the Caduceus, to take the place of the green cross so commonly used by many cults, wish to make a report at the next meeting in December. The A. M. A. has offered to supply these emblems in quantities not less than one hundred, with the words, "Worcester District," across the lower border of the rim, for \$1.20 instead of the regular price of \$1.50. The police departments of Worcester and some of the surrounding towns are willing to recognize the emblem and for cars bearing it will make certain allowances in traffic and parking regulations. This will not, however, include repeated and flagrant violations of these regulations by any member of the Society. The A. M. A. will make every effort to limit the sale of these emblems to members of the Society. Will you give your approval or disapproval of the idea by signing and mailing the enclosed card at once?

The Worcester Medical Milk Commission has issued a card setting forth that certified milk is sold in Worcester and gives the names of the producers.

A. W. ATWOOD, Secy.

THE PETERBOROUGH, N. H., HOSPITAL.—A board of eleven Trustees at Peterborough, New Hampshire, is to have turned over to it next spring a twenty-five-bed institution, in the midst of a ninety-acre tract of land, beautifully situated. The hospital will be very complete and very fine, representing gifts of over \$200,000. The trustees are engaged in a study of hospital problems so as to be prepared to provide the best possible service for the people of that section.

WEEK'S DEATH RATE IN BOSTON.—During the week ending December 9, 1922, the number of deaths reported was 223, against 188 last year, with a rate of 15.22. There were 29 deaths under one year of age, against 29 last year. The number of cases of principal reportable diseases were: Diphtheria, 71; Scarlet Fever, 37; Measles, 75; Whooping Cough, 70; Typhoid Fever, 1; Tuberculosis, 25. Included in the above, were the following cases of non-residents: Diphtheria, 14; Scarlet Fever, 9; Measles, 1;

Whooping Cough, 1; Tuberculosis, 5. Total deaths from these diseases were: Diphtheria, 3; Scarlet Fever, 1; Measles, 4; Whooping Cough, 4; Typhoid Fever, 1; Tuberculosis, 8. Included in the above were the following cases of non-residents: Diphtheria, 2; Scarlet Fever, 1; Whooping Cough, 1; Typhoid Fever, 1; Tuberculosis, 1.

RABIES IN MAN.—Last year in eight different states there were twelve deaths registered from rabies in man, as follows: California 1, Kentucky 1, Massachusetts 1, New York 4, Ohio 1, Pennsylvania 1, Rhode Island 2, Texas 1.—*Buffalo Sanitary Bulletin.*

RADIUM FOR PARIS.—The city of Paris has authorized the expenditure of 2,500,000 francs (a little less than \$200,000) for the purchase of radium for the public hospitals of that city.

ENTRANCE REQUIREMENT OF UNIVERSITY OF PENNSYLVANIA MEDICAL SCHOOL.—Beginning in 1923 applicants for admission to this school must have had three years of college work.

HARVARD MEDICAL SOCIETY.—Meeting in the Peter Bent Brigham Hospital Amphitheatre was held Tuesday evening, Dec. 5, 1922. Program: "Clinical Observations with Henderson's Method of De-etherization," Mr. J. C. White, Harvard Medical School; "Some Remarks on the Lungs in Heart Disease," Dr. C. Lundsgaard, Rockefeller Hospital, New York.

THE COMBINED MEETING OF THE MIDDLESEX SOUTH, NORFOLK AND NORFOLK SOUTH DISTRICTS.

This meeting was held at the Tufts College Medical School Nov. 21st, 1922, and was called to order by Dr. Enos H. Bigelow. Dr. John W. Bartol was the first speaker. He spoke of the responsibility of the profession in matters of legislation affecting public health and the practice of medicine and made a strong plea for more definite interest in the problems before the legislature from time to time.

Dr. James S. Stone discussed the necessity for some extension of the power to license hospitals and explained some of the features of hospital functions which may lead to efforts to have these institutions more generally supervised. He also referred to the work of the Industrial Accident Board in its relation to medical service and called attention to the plans for a special meeting at which speakers would discuss all phases of the care of injured workmen.

Mr. Maurice Caro represented Mr. O'Brien, the district attorney of Suffolk County, and gave an interesting discourse on medical matters from the legal standpoint. About 250 members were present. The meeting was an especially interesting occasion. Refreshments were served after the meeting.

INSTRUCTIVE DISTRICT NURSING ASSOCIATION, BABY HYGIENE ASSOCIATION.

The month of November was characterized by a pronounced and general increase in sickness.

Twenty-six thousand eight hundred and forty-six visits were made by the nurses to 7,720 patients, 2,909 of whom were newly admitted.

This is an increase of 24% in new work over that of November, 1921, a phenomenal jump due not to excessive prevalence of any one disease, but to a notable increase in many.

One of the chief features of the month was the increase in the respiratory diseases, new cases of which rose to 50% more than those of November of last year, the figures being 180 new cases of bronchitis; 135 of pneumonia; 93 of other respiratory diseases. There were also 29 new cases of grippe and 79 of tonsillitis.

Measles also showed an increase, 79 new cases, and whooping cough, 67.

Tuberculosis alone among the chronic diseases showed a slight drop, all the others showing some increase.

Prenatal work has continued to increase, 497 pregnant women being admitted, while more deliveries were attended than during November of last year.

The total number of children now under Baby Hygiene care is 9,366. During the month of November 413 new cases were admitted—an increase of 9% over those of November of last year. Forty-four children were readmitted either at their old stations or at stations in other parts of the city. One hundred and fourteen conferences were held during the month, with a total attendance of 5,010—an average of 44. There was an attendance of 265 at the various classes—posture, nutrition, cooking, etc. Ten thousand and two hundred and fifty-six visits were made by nurses and dietitians, and 60 demonstrations were given by the dietitians to individual mothers.

Obituary.

HENRY WHITMAN KILBURN, M.D.

Dr. Henry W. Kilburn, Boston ophthalmologist, died suddenly at Los Angeles, California, December 3, 1922, aged sixty-five.

The son of John and Amanda Maria (Whitman) Kilburn, he was born at Lonsdale, R. I., April 15, 1857. He was a descendant of Thomas Kilburn, who came to this country from Wood Ditton, Cambridgeshire, England, in 1645, and settled in Glastonbury, Conn. Dr. Kilburn was graduated from Harvard in 1880 and from Harvard Medical School in 1884, supplementing his medical course by a year's study of ophthalmology in Berlin, Germany. On his return he was house officer at the Massachusetts Charitable Eye and Ear Infirmary until the spring of 1887. He was ophthalmic surgeon at the Lowell Corporation Hospital for two years, then assistant ophthalmic surgeon at the Boston City Hospital, and finally ophthalmologist-in-chief to the Carney Hospital from 1897 to 1907. His reputation was of the highest, being known as one of the best refractionists in the community. He was a member of the American Ophthalmological Society, the New England Ophthalmological Society, of which he was president for a year, the Boston Society of the Medical Sciences, the Massachusetts Medical Society and the American Medical Association. He belonged also to the Harvard Musical Association and the University, Progressive and Episcopal Clubs. For many years he lived in West Medford. In 1889 he married Miss Harriet Mason Plumer of Boston.

Dr. Kilburn gave up practice in 1916 and had lived much of the time since in Switzerland, returning to Boston every now and then. His death will be mourned by a large circle of friends.

Miscellany.

A RIFT IN THE CLOUDS.

Frederick Müller, Professor of Medicine in Munich, has been called by many the greatest teacher of medicine in the world. He has done much laboratory work during his career; in fact, his first years were spent in the laboratory of Voit, an older German scientist. Just now, when the Germans (and many Americans) are being criticised widely for lack of humanitarianism in the practice of medicine, the following inspired letter from Munich, signed by Dr. Müller, is distinctly timely:

Dear Dr. Lusk:

You write in a recent letter that Benedict [S. R.] holds it to be an anomaly that I, as a clinician, should concern myself with these physiologic problems. The responsibility for this belongs not alone to my training in Voit's laboratory but also and especially to the circumstance that, as physician at the sick bed, my attention is constantly called to the significance of problems of metabolism, and because

the physiology of metabolism has been stimulated to a remarkable extent through a study of the pathology of metabolism at the bedside of the sick man.

You should read the new book of Petren on diabetes. It suggests a number of new problems. On the other hand, I do not believe that the new English experiments on the subject of carbonic acid and oxygen tension in arterial and venous blood will inform us further. We are investigating the blood of the arteries and veins of the arm. The metabolism of the arm and of the hand is of very little importance in comparison with that of the liver and the kidney or even of the heart. Oh, if we could only compare the blood of the aorta with that of the inferior vena and the hepatic vein! The new experiments of Starling are of much greater clinical importance and are fit to establish upon a new foundation our views concerning circulatory disturbances and heart disease.

The clinical teachers are forced to follow the progress made by the pure sciences—chemistry, physics and physiology—because they throw some light upon the processes of disease in man. But we do not approach the sick bed as physiologists, but rather first of all with love toward the sick man and with an intense desire to help him. I believe that this human fundamental element must be inborn or one will never be the right kind of a physician. The clinical teacher must be primarily a good and experienced physician, and not one whose entire interest and experience are of the laboratory. He who does not heartily interest himself in his patient will never be a good clinician. This human, or, if you will, humanitarian, side of our profession is not only the most beautiful but also the most interesting part of it. It assumes an interest not only for the body but also for the mental individuality of the patient, and I can assure you that my afternoon consultation hours, in which I see patients from all the countries of the world, are to me at least as interesting as the work in my laboratory.

Personal contact with the patients during my consultation hours widens my mental horizon not only from a medical but also from an intellectual point of view, for difficult medical cases and interesting personalities from all classes of society come to me during these hours. I therefore find myself out of sympathy with the new American system of "full-time clinicians," which limits the activity of the clinician to a ward in the hospital and forbids private practice among those who do not wish to go to a hospital. I feel that the forbidding of private practice is not in accord with Holy Writ, as expressed in I Timothy, chap. 5, vs. 18.

FRIEDRICH MÜLLER.

Munich, Aug. 10, 1922.

LOW INCIDENCE OF VENEREAL DISEASE IN OUR COLLEGES.

The Buffalo Sanitary Bulletin comments on the results obtained from a recent questionnaire sent by the United States Bureau of Education and the United States Public Health Service to almost one hundred college presidents and executives, asking for their opinions with respect to the prevailing attitudes and practices of college men in the matter of sex.

Sixty-five replies were received, varying greatly in their comments, but the unanimous opinion was that venereal disease in the colleges is of an extremely low incidence; probably much lower than a generation ago.

"The forces responsible for this change, loosely classified, are, first, education, both popular and academic, in matters of health, with an increasing emphasis on the hygiene of sex and venereal diseases; *second*, a more active concern on the part of the college in the physical well-being of its students, including increased opportunities for physical training and play activity; *third*, improvement in environment factors, such as the elimination of the saloon and the suppression of prostitution, and, *fourth*, the influence of co-education upon the 'atmosphere' of the college."

TRYING TO LIFT THE BAN ON MALT LIQUORS.

Edward & John Burke, Limited, of Dublin, bottlers and distributors of Guinness Stout, have filed a complaint in the United States District Court for the Southern District of New York, asking for an injunction to prevent prohibition officers from interfering with the sale of Guinness Stout for medicinal purposes. This complaint is directed against the Willis Campbell Act, in so far as it prohibits the prescribing of stout for medicinal purposes.

In 1904, according to this complaint, answers to questionnaires were received from 435 reputable physicians, "of whom 96 did not prescribe stout as a medicine, and 339, or 78 per cent., stated that in their judgment stout possessed valuable medicinal qualities, and that they habitually prescribed it for their patients, designating the cases in which they felt it was a proper and useful medicine."

We must ourselves confess that we cannot see why stout with an alcoholic content of from 7-8% should be discriminated against in favor of the more potent liquors.

THE INFECTIOUSNESS OF MEASLES.

Dr. F. A. Sharpe, in commenting upon the recent epidemic of measles at Preston, refers to

the extreme infectiousness of this disease. He points out that, when an epidemic breaks out in a district, practically every child in that district, unless naturally immune, falls a victim to that disease.

During the past 50 years measles has been responsible for 1,413 deaths in Preston; 835 have died from whooping cough, 750 from diphtheria, 678 from scarlet fever, 38 from smallpox, while 3,358 have succumbed to epidemic diarrhoea.

Dr. Sharpe emphasizes the need for protecting infants from the infection of measles, since the mortality from this disease is much higher among infants than among older children.—*The Medical Press and Circular*.

COOK PORK WELL TO AVOID TRICHINOSIS.

"Cook pork well" is the advice of the United States Department of Agriculture. Failure to observe this important precaution is liable to be followed by serious illness known as trichinosis. Hogs harboring the parasites show no symptoms and pork containing trichinae is exactly the same in appearance as other pork. No practicable system of meat inspection has been discovered by which persons who eat uncooked or imperfectly cooked pork can be protected from the danger of trichinosis. Cooking destroys the parasites.

The winter season, particularly during the holidays, is when outbreaks of trichinosis are especially likely to occur. At this time of year, smoked and dried sausage and various other products made from pork and eaten without cooking are commonly consumed in considerable quantities in many households, in which the eating of uncooked pork is customary. Entire families may be stricken and as many as a hundred cases of trichinosis have resulted from the meat of a single hog served as uncooked sausage or similar product at some gathering or reunion of people, only those escaping who did not eat any of the uncooked pork. The comparative rarity of the disease may present diagnostic difficulties.

The prevention is obvious and consists in thorough cooking.

Correspondence.

DARWINISM AND EVOLUTION. THEIR RELATION TO THE PHYSICIAN.

East Boston, Mass., Dec. 2, 1922.

Mr. Editor:

The BOSTON MEDICAL AND SURGICAL JOURNAL of November 30th, 1922, contained a few paragraphs under the heading of "Darwinism versus Christianity Again." It referred to a recent conference held by

various Protestant clergymen in St. Paul, Minnesota, where it was decided to oppose the teaching of Evolution in the public schools of that state. At this meeting Evolution was spoken of as "antiscientific and antiscientific theory of the origin of man and the universe."

The JOURNAL then remarks that "although there may be difference of opinion relating to the theories of Evolution it is open to question whether the decision relating to the interpretation of scientific data should be left with the clergy, for there is not sufficient evidence at the present time indicative of an adequate amount of study on the part of the clergy that would warrant leaving the interpretation of the evidence to this body of men. Furthermore, many scientific minds have not found in the theory of Evolution any conflict with religious teaching."

Now it is most important that every physician should have a clear idea of what "Darwinism" and "Evolution" mean. We need not enter into a discussion of Darwin's attitude towards Christianity or the worship of any supernatural being with the hope of future rewards or fear of future punishment. That is beyond the scope of this JOURNAL and does not concern this article.

But Evolution and Darwinism concern not only all physicians but every man and woman who would have an intelligent conception of the origin of our universe. It is surprising to find the large number of medical men who have absolutely no idea of what Evolution means or of the great work accomplished by that great quartette of scientists, Darwin, Huxley, Spencer and Haeckel. Evolution is continually being spoken of by such men as "that monkey theory."

It is the object of this article to briefly outline what we mean by Darwinism and Evolution, with the hope that medical men may extend their knowledge to their further advantage on the subject. A Kentucky legislature, when asked to make a state law, excluding all teaching of Evolution from the public schools, rejected that measure by but one vote. Massachusetts may yet be called upon to decide the question and it behooves the medical fraternity to have at least a fundamental knowledge of the subject.

First, let us ask, how are we going to find out the truth, in so far as it is obtainable, in regard to any and all subjects? What are the methods which we shall adopt? Professor Huxley has left us a formula which is applicable to all propositions. Condensed, it is as follows: "Observe and gather all facts. Experiment with them, classify and compare them, eliminate useless facts, deduct conclusions and then try to verify all conclusions."

Now what do we mean by Evolution? Again, briefly, we mean that all living plants and animals had a common ancestor and originated from one or more simple forms. It means that a unifying principle underlies all phenomena, whether of earth or air, sea or star or human mind. It means organized knowledge for the purpose of utility and for the further acquirement of knowledge.

The idea of Evolution has been in the minds of men for centuries, sages of past time were mindful of it, Greek philosophers guessed at it and the early church of the Christians defended it.

The following incident should be remembered. It is a good one on the theologians. In the year 384, (Christianity now being a state religion and growing in power) the old pagans sent their most distinguished orator, Symmachus, to Milan, to plead with the Christians that they be allowed to retain their old deities.

Behind the throne of the boy Emperor Valentinian, stood Saint Ambrose, the greatest Christian leader since Saint Paul. And the famous argument by which Ambrose silenced the pagans was in effect the Evolutionary argument. It was an appeal against conservatism to the constant changefulness and progress of nature.

Ambrose looked round the world for what we should call, in modern language, the laws of nature, and he found the supreme law was change. "Was religion alone," he asked, "to be an exception to the law?" "Were they to cling to old rites and legends when the voice of nature on every side spoke of change, advance, the death of the old, the birth of the new?"

Saint Ambrose won, but the church, ever since has forgotten his argument. It has proven too much.

The rhetorical argument of Ambrose has now become a science and the most conspicuous, the most comprehensive, the most illuminating law of nature is Evolution. From the atom of matter to the star, from the little alga swimming in the pond to the orchid, from the worm to the human being, from Niagara to the Alps, from the primitive Bushmen to the civilization of the United States—all was evolved. Religion is no exception.

Men may dispute as to whether things were evolved gradually or by spurts, whether the correct way to conceive the Evolution is Lamarckism, or Weismannism, or Mendelism or Darwinism, but the fact and universality of Evolution remains. All subjects fall under the law and it has revolutionized or profoundly modified every department of human thought and every motive to human action.

The idea of the origin of species by the modification of pre-existent organisms had been in the minds of men long before Darwin.

Linnaeus, Buffon, St. Hilaire, Lamarck, Goethe, Lyell, and Erasmus Darwin had all seen it, but Charles Darwin recognized its universal application where others had seen only the particular.

"Darwinism" refers chiefly to his development of what he calls "Natural Selection," the phrase which has caused so much controversy. He states it as follows, ("Origin of Species" page 74). "This preservation of individual differences and the destruction of those which are injurious, I have called NATURAL SELECTION or the survival of the fittest." It accounted for the development of new species. It did not explain all, the wonder is that it explained so much. Darwin did not expect that it would explain everything, but it has explained so much and been so valuable, that it can never be discarded. The phrase "survival of the fittest" was coined by Herbert Spencer, and meant that those organisms which could best adapt themselves to their environment would live. And "natural selection" meant that the organism retained all useful habits and structures that helped it to survive and discarded all that would prevent it from living.

Professor Huxley in England and Ernst Haeckel in Germany, took up and applied the theory of Evolution to their respective departments—and what happened? Men of science in all lines were obliged to reconstruct old ideas and adapt them to Evolution.

Darwinism and Evolution were thus the great moving causes in a great scientific revolution and in the vast onward movement of the human intellect. By these means, science, which had been in a more or less chaotic maze up to 1860, was placed in an orderly system with a definite plan and recognizable meaning. And Charles Darwin produced a greater change in current thought than any other man. He accomplished this by observing nature with a strength of purpose, tenacity, honesty, and ingenuity, never surpassed.

No question can now be considered fairly or completely without looking into its evolutionary aspect. It has opened up a large field for investigation and has placed science on a firm footing; in fact, all modern advancement owes its debt to the idea of Evolution. And without it the science of medicine would still be in the stage of the dark ages.

It is high time that medical men asserted themselves, for they have been asleep too long, especially in matters of education. *The interpretation of the*

facts of Evolution should be with men trained in the natural sciences, not with theologians. The minds of dead men of an obscure past should not rule the present or the future unless their teachings have been verified by repeated experiment.

An education in the essentials of science is the one thing most needed by this or any other country. *Verified facts, based on sufficient and best evidence should be sought after.* The doubter, the sceptic, the questioner, all are needed for the advancement of the human race.

No one knows for certain how this universe of ours originated. We have two explanations, one given by theologians and the other by science.

The one given by the former depends upon the guess of primitive and savage man of a low type of mentality to explain the phenomena of nature; the other, Evolution, given by men of science, with trained minds, who have carefully weighed and tested all available evidence to the end that nothing but the truth shall prevail. One leads to mental slavery and retrogression, the other to progress. I believe Saint Ambrose was right.

J. DANFORTH TAYLOR, M.D.

COMITÉ D'AIDE DE L'UNION DES AVEUGLES DE GUERRE.

25, RUE BALLU, PARIS, (IXE)

Authorized by Governmental decree, April 9, 1921.

Mr. Editor:

I am enclosing a letter from my very good friend Theodore C. Merrill, an American physician now permanently engaged in research work in Paris. I can vouch cordially for Dr. Merrill's good judgment and enthusiasm and also for his earnest work in promoting the Entente Cordiale between American and French physicians. I know that this union for the French war victims who have lost their sight is doing splendid work with terribly limited resources. If there are kind hearted physicians whose eyes may fall upon this letter in the JOURNAL, it is possible they may be induced to contribute to so worthy a cause. On account of my personal knowledge of the great need of this work I shall be especially appreciative if you can give the matter space in the JOURNAL.

Very sincerely yours,

KENDALL EMERSON.

21 High St., Worcester, Mass.

Paris, November 15, 1922.

Dear Colonel Emerson:

I want to ask you kindly to aid and further efforts which I am making in behalf of the Oeuvre indicated in the heading. The Union des Aveugles de Guerre maintains a foyer, or home centre, for the war blinded, where the ex-soldiers may find recreation, a Braille library, aid in securing raw material and employment, and in disposing of their finished articles. Temporary lodging and care are also provided for necessitous cases, and a rest home for the families of the indigent blind is planned. The immediately urgent problem is to keep the centre running.

Coöperating with Doctor de Lapersonne, I am making an appeal to American ophthalmologists and oculists, Doctors de Schweinitz, Wilmer and McReynolds have cordially accorded me their hearty support and I trust that a notice will soon appear in the *Journal of Ophthalmology and Journal of the A. M. A.* Doctor William W. Keen has also kindly helped me. If you can kindly bring this matter to the attention of local ophthalmologists, oculists or any others who may be interested, your kindness will be most deeply appreciated by the Union and its blind. You may

note from the heading that I am serving as Delegate for America. I have arranged with the Guarantee Trust Company to receive all funds which I may handle. New York drafts, or certified checks, made in dollars and payable to me, will constitute the best form for transmitting contributions. On the part of the French, efforts will be continued all the time. You are quite familiar with the many needs pressing in France, and that may be left in your experienced hands. Speak a good word for the Union whenever you can, dear sir, and find some people who are able and willing to aid this group of the war blinded, who have unquestionably given highly in the cause of the world's freedom and justice.

Please accept my very best wishes for a happy Christmas and the cordiallest of regards from the banks of the Seine.

Most truly yours,

THIBODEAU C. MERRILL,

Delegate for America of the
Union des Avengés de Guerre.

10 bis rue Herran, Paris, XVIIe.

NEXT MEETING OF THE AMERICAN SURGICAL ASSOCIATION.

Mr. Editor:

I note in THE BOSTON MEDICAL AND SURGICAL JOURNAL of November 30, a statement that the next meeting of the American Surgical Association will be held in Rochester, Minn., in January, 1923.

I am not sure of the source of this report, but it is incorrect, as the date of the meeting has been decided only recently, and the meeting will be held in Rochester, Minn., May 31 and June 1 and 2, 1923.

Sincerely yours,

R. B. GREENOUGH, Secretary.

HUMAN ACTINOMYCOSIS.

December 6, 1922.

Mr. Editor:

I am endeavoring to make a complete study of the distribution of human actinomycosis in this country. The number of cases reported in the literature is surprisingly small, and I know that the disease is not so rare as is sometimes thought. I shall greatly appreciate hearing directly from any one who has had experience with this disease, and desire to know concerning case histories the following: age, sex, occupation, residence, state in which the disease was contracted, location of lesion, duration of symptoms, and any special points of interest connected with the treatment, outcome of the disease, or necropsy findings.

A. H. SANFORD, M.D.

Mayo Clinic, Rochester, Minnesota.

THE TREATMENT OF PNEUMONIA.

December 10, 1922.

Mr. Editor:

I venture to send enclosed clipping in view of your editorial on Pneumonia in your issue of Dec. 7, 1922. I trust you may find it worth reading and reprinting in part. In looking back, I have lost very few cases in private practice, where I was attending physician and patients followed my advice from the beginning.

Yours sincerely,

BEVERLEY ROBINSON.

NOTE:

The clipping* is an editorial analysis of three papers published by Dr. Robinson.

The points made are as follows: Since the pneumococcus is found in the secretions of the mouth and throat of many healthy persons one special indication

is for the use of antiseptic gargles with an acid reaction. Second, on the development of chill, fever, pain in the side, cough and expectoration beechwood creosote should be vaporized in the patient's room; third, prevention of contagion; fourth, adequate ventilation; fifth, two nurses; sixth, proper food (mainly milk) with abundance of water; seventh, avoidance of extremes in treatment, especially mentioning digitalis and strychnine.

He believes in the use of quinine, and antimony when the congestion and proxia are prominent features. Alcohol should be used judiciously except in cases of plethoria and hepatic engorgement and its effect is good in association with coffee. He also believes in nitroglycerine in cases with marked pulmonary congestion and oedema.

In a later communication especial endorsement is given to the sublingual use of strophanthin.

In a few words he endorses the use of most of the drugs that have been used when definitely indicated except aconite and digitalis.

IN MEMORIAM

LOUIS PASTEUR.

1822—1922.

The milestones of a century of strife

Have passed from sight along this road of time

Since France first offered to mankind a life

That service to mankind has made sublime.

In spite of stiff-backed dogma, worn and old,

In spite of jealousy and hatred blind,

You made the mysteries of earth unfold

Before the patient searchings of your mind.

Made clearer by the light your genius shed,

The light-deflecting crystals you have shown

To have a meaning until then unread,

And Chemistry has claimed you for her own.

The wines that all of France have prized so much,

Regained their sweetness when your goal was won;

The silkworm recognized your magic touch

And at your bidding threads of gold were spun.

As ripples widen in a placid pond,

Your tasks, diversified, still met success.

Disease retreated when you waved your wand.

And grateful nations learned your name to bless.

Pasteur, we hail you in that far beyond

That wisely, still, is veiled from mortal glance.

May gratitude intensify the bond

That grows between America and France!

JOG.

*Medical Record, February 25, 1905.

DIABETES AND ITS SURGICAL COMPLICATIONS.

A meeting of unusual interest both to physicians and surgeons is that to be held in the Boston Medical Library on Wednesday, December 27. Our knowledge of diabetes has increased tremendously of late years. The prospect of arresting the disease and of prolonging life had been very bright even before the discoveries of the last few months regarding insulin.

One of the causes of death in diabetes has been the surgical complications. The progress in medical treatment has made possible corresponding progress in the surgical treatment of diabetic lesions.

Improved methods of anesthesia have greatly lessened operative mortality. The ability to get patients sugar free, even for limited periods of time, has rendered possible the healing of operative wounds which otherwise might never have healed. Much more conservative surgery has been made possible.

At this meeting arranged by the Surgical Society of the Suffolk District Society, the chief speaker will be Dr. E. P. Joslin, one of the leading authorities upon diabetes. Following his presentation of the subject representative surgeons from the leading Boston hospitals will summarize their experience in the operative treatment of diabetic lesions.

This meeting, to which all physicians are invited, will teach us what is possible under the improved methods which have already been established. We may get an inkling of what can reasonably be expected from the startling developments of the last few months.

SOCIETY MEETINGS.

DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue.

Barnstable District:—Hyannis, —February 2, 1923. (Annual Meeting)—May 4, 1923.

Bristol South District:—Fall River, —May 3, 1923.

Essex North District:—Haverhill, (Semi-Annual Meeting)—January 3, 1923. Y. M. C. A. Building, Lawrence. (Annual Meeting)—May 2, 1923.

Meetings of the Suffolk District and the Boston Medical Library, at the Library:

December 27, 1922:—Surgical Meeting. "Surgical Lesions Occurring in Diabetes: Their Peculiarities and Management," Dr. Elliott P. Joslin, Boston. An account of the experience in this field of the major hospitals of Boston, by members of the staffs.

January 31, 1923:—Medical Meeting. "Epidemic Encephalitis," Dr. E. W. Taylor, Boston.

February 28, 1923:—Medical Meeting. "Colitis," Dr. Henry F. Hewes, Boston.

March 28, 1923:—Surgical Meeting. "A Review of What Surgery Can Accomplish in Diseases of the Thoracic Organs, with a Forecast of the Future," Dr. Howard Lilienthal of New York.

April 25, 1923:—Annual Meeting. Election of Officers. "The Record of the Past Twelve Years in Syphilology, with a Forecast of the Future." A series of 10-minute papers. Dr. C. Merton Smith, Boston, will preside.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexia Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, Hist. The date for each speaker has not been assigned.

Middlesex North District:—Meeting, Wednesday, January 31, 1923.

Middlesex East District:—Jan. 24, 1923. The Nursing Problem. Speaker to be announced later.

March 21, 1923. Mental Factors in Childhood. Paper by Dr. William Healy.

April 18, 1923. Interpretation of Laboratory Findings. Papers by Dr. E. G. Crabtree and one to be announced later.

May 9, 1923. Annual Meeting.

All meetings except the annual meeting will be held at the Harvard Club in Boston. A. E. Small, Secretary.

Worcester District Meetings are scheduled as follows:

January 10, 1923:—The meeting will be held at the Worcester State Hospital, Belmont Street, at 4.15 P.M. Programme: "A Discussion of Status Thymico-Lymphaticus and the Inherent Compensatory Possibilities," Dr. Walter Timme, New York City. Discussion will be opened by Dr. W. A. Bryan.

February 14, 1923:—The meeting will be held at the Worcester City Hospital at 4.15 P.M. The programme will consist of a series of papers by members of the staff.

March 11, 1923:—The meeting will be held at St. Vincent's Hospital at 8.15 P.M. The programme will consist of a series of papers by members of the staff.

April 11, 1923:—The meeting will be held at Memorial Hospital at 8.15 P.M., and the programme will consist of a series of papers by members of the staff.

May 9, 1923:—Annual meeting and banquet.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

December 26-30, 1922:—American Association for Advancement of Science meets in Boston.

January, 1923:—Massachusetts Society of Examining Physicians (date and place undecided); Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston; W. H. Allen, Mansfield, Mass., Secretary.

January, 1923:—Boston Association of Cardiac Clinics. Meeting January 18, 1923, at 8.15 P.M. Boston Lying-In Hospital (New Hospital). Subject: Pregnancy and Heart Disease.

January, 1923:—Boston Medical History Club will meet January 15, 1923.

February, 1923:—New England Dermatological Society Meeting, February 14, 1923, at 3.30 P.M., in the Skin Out-Patient Department, Massachusetts General Hospital; C. Guy Lane, Secretary.

February, 1923:—Boston Medical History Club will meet the third Monday of this month.

March, 1923:—Massachusetts Society of Examining Physicians (date and place undecided); Hilbert F. Day, Secretary.

March, 1923:—Boston Association of Cardiac Clinics. Meeting March 15, 1923, at 8.15 P.M. Boston City Hospital. Subject: Prevention and Relief of Heart Failure.

March, 1923:—Boston Medical History Club will meet the third Monday of this month.

April, 1923:—New England Dermatological Society Meeting, April 11, 1923, at 3.30 P.M., in the Surgical Amphitheatre, Boston City Hospital; C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston; W. H. Allen, Mansfield, Mass., Secretary.

April, 1923:—Boston Medical History Club will meet the third Monday of this month.

May, 1923:—Massachusetts Society of Examining Physicians (date and place undecided). American Pediatric Society Meeting, May 31, June 1 and 2, 1923, at French Lick Springs Hotel, French Lick, Ind.; H. C. Carpenter, Secretary.

May, 1923:—Boston Association of Cardiac Clinics. Meeting May 17, 1923, at 8.15 P.M. Children's Hospital. Subject: Rheumatism and Chorea and Heart Disease.

June, 1923:—American Medical Association, San Francisco, June 25-29, 1923; Alexander R. Craig, Chicago, Ill., Secretary.

July, 1923:—Massachusetts Association of Boards of Health, July 26, Nantasket; W. H. Allen, Mansfield, Mass., Secretary.

*Deceased September 2, 1922.

DR. W. T. GRENFELL, superintendent of the Labrador Medical Mission of the Royal National Mission to Deep Sea Fishermen, was recently admitted to the Fellowship of the Royal College of Surgeons, England.—*The London Press and Circular*.

WHY DO THEY LEAVE?—Only 13 of every 100 children entering the first grade of the public schools remain to complete the twelfth grade, or the last year of high school. Of 100 children entering the first grade 86 reach the fifth, 73 the sixth, 64 the seventh, 58 the eighth, 32 the first year of high school, 23 the second year, 17 the third year, and 14 the fourth year, with 13 remaining to graduate.

—[*American Education Week*.

Gastron

An entire gastric gland tissue juice

The activating, enzymic and associated organic and inorganic substances and principles of the entire gland, extracted in an acid-aqueous-glycerin medium; alcohol free, sugar free; a grateful, agreeable solution.

Of wide service clinically—gastric insufficiency, acute gastric disorder, irritability, intolerance of food; under all conditions where gastric function is disturbed or in abeyance—from fatigue, shock, care.

Fairchild Bros. & Foster
NEW YORK

DIPHTHERIA ANTITOXIN *and* DIPHTHERIA TOXIN-ANTITOXIN

PHYSICIANS have been specifying Parke-Davis Antitoxin for twenty-five years because it is dependable. In a disease in which life or death hinges on prompt and adequate immunization nothing must be left to chance. The patient has a right to every possibility of recovery; anything short of this would be false to the ideals of medical practice and subversive of the rights of humanity.

Medical men prefer Parke-Davis Antitoxin because it is pure, free from contamination, and certain of action. The potency and purity of

the product are assured by every means known to biological science.

Toxin-Antitoxin, P. D. & Co., is rapidly winning similar recognition.

Active immunization is the end sought, and safety and efficiency of the product are predicated on proper mixing of the toxin and antitoxin. An improper mixture would result either in failure to protect, or in a dangerous reaction. Our Toxin-Antitoxin is so balanced as to insure the maximum immunizing effect consistent with safety.

"DIPHTHERIA IMMUNIZATION," a reprint, sent on request. Write nearest branch: Detroit, New York, Chicago, Kansas City, Baltimore, New Orleans, St. Louis, Minneapolis, or Seattle.

WHAT MAINE SAYS

....., Maine,
Nov. 26, 1922.

Dear Sirs:

The Taylor Massotherapor I bought from you a few weeks ago is without doubt the most wonderful "result getter" in chronic catarrhal ears, with beginning deafness, that has ever come to my attention.

I am not in the habit of writing testimonials and this isn't a testimonial, only a confession, as I harbored the thought after I had given your agent the order that I was stuck again; but I can assure you that I will meet him with a glad hand if he ever hits the Arcostook trail again.

Anyway send me another one at once, and oblige,

..... M.D.

THE THOMAS-SINCLAIR ABDOMINAL SUPPORT

(Patents Pending)

The illustrations show an extreme case of obesity to which **The Thomas-Sinclair Support** has given relief and comfort. In conditions of this type a strong, durable, unyielding support is necessary. With this we have combined the feature of the side opening and minimum number of straps, which simplifies effort in putting on and adjusting the Support. In this particular case suspenders are necessary to prevent slipping as the wearer has no hips or posterior on which to purchase the Support. Ordinarily no suspenders are required.

The Management of an Infant's Diet

Mellin's Food contains 58.88 per cent of Maltose
Mellin's Food contains 20.69 per cent of Dextrins

a proportion of

Maltose and Dextrins

best suited to the carbohydrate needs of the average baby.

Mellin's Food contains 10.35 per cent of Cereal Protein.

Mellin's Food contains 4.30 per cent of Salts which consist mainly of Potassium Salts, Phosphatic Salts, and a small amount of Iron.

These facts should be considered in selecting a modifier of milk for infant feeding and these facts point out some of the reasons for the success of Mellin's Food which probably is unparalleled in any decade since the beginning of the study of scientific infant feeding.

Mellin's Food Company, Boston, Mass.

The Romance of Radium

3. Comparison of Ores

THE European pitchblende ores with which Madame Curie worked yielded about one gram of Radium to every five or six tons. In the case of our Colorado-Utah ore, (Carnotite) 400 to 500 tons are required to produce a gram of

Radium, and to secure this amount of milling ore, it is necessary to hand sort it from several thousand tons of worthless material.

Our Service

An immediately available supply of standard radium tubes, needles and plaques, under seal of the United States Bureau of Standards; quality guaranteed by the Standard Chemical Company, the pioneer American and world's largest producer of radium.

Necessary instruments and screens for the safe handling and application of radium.

A comprehensive and scientific course of instruction in the physics and therapeutic use of radium.

A loose-leaf Compendium of Abstracts of professional papers showing the technical results of radium treatment, with supplements as issued.

"RADIUM"—a quarterly journal, the oldest publication devoted exclusively to the therapeutics of radium.

Complete installations of the latest apparatus for the collection, purification, tubing and measurement of radium emanation.

Medical and technical experts always available for conference or for advice by letter.

Skilled assistance in seeking lost radium.

In spite of this apparent handicap the Standard Chemical Company has led the world in the production of Radium, being the pioneer American and world's largest producer.

AN ADDRESS AT THE CELEBRATION OF THE FIFTIETH ANNIVERSARY OF THE ESTABLISHMENT OF THE TRAINING SCHOOL FOR NURSES AT THE NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN, OCTOBER 31, 1922.

BY ALFRED WORCESTER, A.M., M.D., WALTHAM, MASS.

THIS is a notable occasion. Fiftieth anniversaries, whether of persons or of institutions, are always interesting. But today we celebrate no ordinary event.

Among the many beneficent services rendered by the New England Hospital for Women and Children, the most noteworthy is the establishment here of the first American training school for nurses, in September, 1872. Other hospitals preceded this in the "treatment of the diseases of women and children and in giving clinical instruction to female students of medicine," as two of the three purposes of this Hospital are stated in its Act of Incorporation.* But in the third purpose, as stated in this same Act, that "of training nurses," this Hospital has absolute priority.

For, although nine years intervened between the acceptance of the Act of Incorporation and the establishment of their training school, this

purpose was kept steadily in view by the noble company of women who founded this Hospital and guided its early development. And as soon as a building was secured, suitable for the enterprise, this training school was begun.

In the Annual Report for the year ending September 30, 1872, the secretary, Mrs. Ednah D. Cheney, says regarding the Education of Nurses: "In order more fully to carry out our purpose of fitting women thoroughly for the profession of nursing, we have made the following arrangements:

"Young women of suitable acquirements and character will be admitted to the Hospital as school nurses for one year. This year will be divided into four periods; three months will be given respectively to the practical study of nursing, in the medical, surgical and maternity wards, and night nursing. Here the pupil will aid the head nurse in all the care and work of the wards under the direction of the attending and resident physicians and medical students. A course of lectures will be given to nurses at the hospital by the physicians connected with the institution, beginning on January 21, 1873.Certificates will be given to such nurses as have satisfactorily passed a year in practical training in this hospital."

And in the same report, Dr. Lucy E. Sewall says:

"Our plan is to take them in for one year, training them thoroughly, theoretically and practically; teaching them medical, surgical and

*Approved March 12, 1863.

confinement nursing. At the end of the year, if we are satisfied with their behavior and their knowledge, we shall give them certificates signed by the hospital doctors."

This announcement of a real training school for nurses is the first of thousands of similar announcements since made in this country, and such leadership in one of the great advances of the last half century is a high honor for this hospital.

But the claim of priority for this school does not rest solely upon this early announcement of intentions, nor yet upon the purpose of training nurses, as stated in the Act of Incorporation nine years earlier. A still more solid foundation for the claim is to be found in the same report, for the year ending September 30, 1872, in this statement:

"At present we have five nurses in training."

No other American hospital fifty years ago could have published any such statement. And yet, in spite of the undisputed fact that the diploma given to one of these five pupil nurses, Linda Richards, is the earliest dated American diploma, the priority that rightly belongs here has been claimed for the Bellevue training school. It will be interesting, by the way, to see what date they will select for their golden jubilee.

That the great New York institution should ignore this brave little pioneer school in Roxbury is not unnatural. Such treatment of the small by large institutions is not unprecedented. But what excuse is there for a former superintendent of this earliest school in America, who publicly controverts its priority and argues in favor of Bellevue's spurious claim?

If this fiftieth anniversary celebration does nothing more than to establish the rightful claim of this school to American priority, it will not have been held in vain. And before another half century shall elapse this cradle of trained nursing in this country ought to be, and doubtless will be, visited as a shrine; just as pilgrimages now are made to the tiny summer house in the garden of Kaiserswerth where Flie'dner's training school began less than two score years before.

When we think of what nursing was before its renovation, and when we remember what the world owes to Theodor Flie'dner and to Florence Nightingale, it is easy to see why every slightest claim to American priority in the movement should be magnified.

Not only have hospitals been redeemed from the pest holes that they were, but in private homes, as well, countless lives have been saved, untold suffering has been assuaged, and in thousands upon thousands of instances the other members of the family have been relieved of the heavy and anxious burden that otherwise would have laid them low.

Next to the discovery of anaesthetics, and then to the discovery of the principles of asepsis,

the advance of medical science, during the last three or four score years, is due most largely to the introduction of trained nursing. And in the latest beneficent advance, in the prevention of diseases and in safeguarding the public health, it is not too much to say that the assistance of trained nurses is absolutely indispensable.

In the history of trained nursing much of the confusion, as well as the conflict regarding priority, is due to the difficulty of distinguishing modern nursing from what preceded it. For instance, in years gone by when Dr. Susan Dimock was credited, as she should be, with the honor of starting this school, Dr. Zakrzewska used to ask why the nurses she herself had trained in preceding years should be so left out of account. And, indeed, in her case, that was not an easy question to answer. For she herself was an excellent nurse and an excellent teacher of nurses. To begin with, before she acquired her medical education, she was an expert midwife and teacher of midwives. And a highly trained midwife is both an obstetrician and an obstetric nurse.

It is therefore no wonder that many of Dr. Zakrzewska's nurses, whom she trained in the earlier years of this Hospital, were afterwards in great demand and held in high public favor. But, even so, it was difficult in those early years to find enough women willing to work here in these wards the six months that were then required before certificates were given them.

The fact is that the training, as then given, was not what ambitions and intelligent women wanted. It was all practical enough, no doubt. They were taught what to do and how to do it, but they were not taught *why*. This is the fundamental difference between a trade and a profession—between old-time and modern nursing—between Dr. Zakrzewska's apprentices and Dr. Dimock's pupil nurses.

In the history of other hospitals, where the change was more marked, there is no such difficulty as here in distinguishing between the old and new kinds of nurses. In the Bellevue Hospital, for instance, at least part of their supply of nurses used to come from the notorious Five Points criminal court, where prostitutes were given the option of a jail sentence or a term of service as nurses. Their conduct in these wards easily can be imagined, even without Dr. Austin Flint's testimony that in his interne days it was no uncommon occurrence of a winter morning to find a nurse lying drunk under the bed of her dead patient whose stimulants she had stolen.

No wonder is it that Bellevue gratefully remembers Dr. Gill Wylie's report of the new order of English nurses and his letter from Miss Nightingale, giving advice and instructions, and the rescue effected by the State Charities' Aid Association, and the advent of Sister Helen. But these events, which led to the establishment

of the Bellevue Hospital training school, in the spring of 1873, do not give it the priority that has been wrongfully claimed for it.

It is my good fortune distinctly to remember Dr. Dimock's arguments in favor of the new school she was about to open. In trying to persuade my mother to allow one of my older sisters to enter this school, she insisted that the vocation of nursing was entirely suitable for *young* women, for *well educated* women, and for those *having all home advantages*. Nursing, she claimed, was no longer to be a trade of last resort for middle-aged spinsters and impecunious widows.

Fifty years ago that was heresy. We can now see that it was true prophecy. But where did Dr. Dimock get these ideas?

As a medical student here, five years before, she, of course, knew the difficulties of the nursing situation in the hospital, and also the insistent public demand for a larger supply of first-class nurses. That she was intent upon the problem is proved by her visits to Kaiserswerth and to Florence Nightingale. She was seeking the light and she found it.

Twenty-five years afterwards, I found that Susan Dimock's enthusiastic plans and hopes were well remembered by Miss Nightingale. Dr. Dimock, indeed, was not the kind of person easily forgotten! And I doubt not that Miss Richards will tell us that her own cordial reception by Miss Nightingale was due at least in part to the fact that she was Dr. Dimock's former pupil, as well as the first American graduate nurse.

It is no mere coincidence in the Report of this Hospital for 1872, from which I have already quoted, that Dr. Lucy E. Sewall, one of the attending physicians, describes as "one of the pleasantest events of the year the return from Europe of Dr. Dimock to take charge of the Hospital." And very naturally, in the following paragraph, Dr. Sewall goes on to say that "we have now determined to use our increased facilities to the utmost and each year to send out a small band of trained nurses."

One of the very small sized objections that has been made against the claim of priority for this training school is the fact that in its first years it was under the immediate superintendence of a physician, and not of a trained nurse. This tries one's patience, especially if it comes from the Bellevue Hospital, where Linda Richards, after her training here, was immediately employed as head night nurse and then as chief nurse of the maternity department. No such objection was then made there, nor afterwards at the Massachusetts General and at the Boston City Hospitals, nor yet at the dozen other hospitals where Miss Richards subsequently was called to establish their training schools.

Trifling as this objection is, it nevertheless

gives occasion to discuss the tendency of the so-called leaders of the nursing profession toward absolute independence of the nursing from the medical profession.

This is dangerous doctrine. But, happily, no such nonsense has been current in this hospital. For here it could hardly be denied that women physicians, especially the many who previously have had regular nursing training, are not excellent nurses.

The fact is that many physicians always have been first-rate nurses, and still more of them are perfectly able to decide between the excellent nursing service sometimes obtainable for their patients and the wretchedly incompetent service they too often have to put up with. The converse is also true, that nurses are often able to distinguish between good and poor doctors. So it is in the army, where many of the officers have been, and might again be, good privates, and, at any rate, where they all can tell a good soldier from a poor one, and where also the soldiers can generally decide rightly which of their officers are capable and which are not. But this does not militate against the proper relationship between officers and privates, nor should it do so between nurses and the doctors they serve under.

The one important fact, and the corner stone of the foundation of modern medical and nursing joint service, is that nursing is only a subordinate branch of medical practice. The nurse, first, last, and all the while, is only the doctor's assistant. He is the captain and she is his executive officer. As his lieutenant, in his absence she, of course, acts for him.

The patient's interests both doctor and nurse must hold in common and always hold above their own interests. And this obligation requires perfect coöperation. Any antagonism, any disloyalty, between the doctor and the nurse harms them both, and also, and far more grievously, harms the patient.

This is only a paraphrase of Florence Nightingale's immortal teaching. And I repeat it today only to emphasize our gratitude to this hospital for its faithful adherence to these principles.

I am sure that I am voicing the judgment of my medical brethren of Massachusetts in testifying to the uniform excellence of the nurses who have had their training in the New England Hospital for Women and Children. They have proved themselves to be loyal and faithful. And, with very few exceptions, they have withstood the ultra-professional tendencies of modern nurses toward their fictitious independence of the medical profession.

To have thus maintained this high standard of nursing service is higher honor for this training school than even its American priority.

With our heartiest felicitations, on this its fiftieth birthday, and with our deep gratitude

to its distinguished founders and able managers, we join our most fervent good wishes for its continued success and ever-increasing glory.

THE IMPROVEMENT OF HEALTH CONDITIONS IN RURAL COMMUNITIES.

BY M. VICTOR SAFFORD, M.D., BOSTON.

As has been suggested by the report of the Committee of the Massachusetts Medical Society "to investigate health problems in relation to the care of the sick in rural communities," the difficulty in securing satisfactory medical care in the rural communities is fundamentally economic in character. The physician avoids the rural communities because they do not give him an adequate return on the investment represented by the cost of a modern medical education.

There is no difficulty in securing competent physicians, and nurses and hospitals to provide up-to-date medical and surgical care for mining camps, rubber plantations or other industrial organizations in the remotest parts of the world whenever reasonable compensation for such services is forthcoming.

If a Massachusetts community is going to have facilities for up-to-date medical care, physicians, nurses and opportunities for dispensary or hospital treatment, somebody has got to pay for them. Furthermore, somebody has got to pay to educate the complaining communities to appreciate and make intelligent use of facilities for up-to-date medical care even if such facilities could be furnished free of cost. An occasional howl of disappointment when somebody finds himself unable to secure a doctor promptly to relieve pain or help to take care of a sick, burdensome dependent is not to be mistaken for an intelligent demand on the part of a community for proper medical care for that community. A large part of the so-called public health work in Boston or any other big city today is devoted to more or less unsatisfactory effort to induce people to make use of facilities for medical care which are available for them.

Medical care and educational work in these Massachusetts communities which are complaining of lack of doctors should be paid for by those who will most directly and most obviously benefit therefrom—by the people of the community itself if possible, but if not, by the people of the geographical district of which the community forms a part. If the people of the district are financially unable to provide proper medical care and medical education for themselves the first thing to do is to so improve the economic condition of the people—to so increase the average per capita purchasing capacity of

the people—that they as a whole may be able to do so. It is not to be expected that every individual will be able to contribute equally for this purpose. The minority in every community always have had to and always will have to look out for those who do not possess the capacity to properly look out for themselves or their interests, if the interests of the latter are to be looked out for at all.

We must not assume that the medical needs of these communities may be supplied by the State, the Medical Society or the Red Cross. An attempt to remedy a situation due fundamentally to unsatisfactory economic conditions, without attempting to improve these economic conditions, is not only economically wrong, but will not produce any permanent practical results in the way of the promotion of public health. Our experience in Porto Rico furnishes a good illustration of the uselessness of expenditures for medical care and health work without remedying underlying unsatisfactory economic conditions. In the Massachusetts rural medical problem there is even less excuse for State expenditures than in Porto Rico. Epidemic diseases, polluted soil or polluted water supplies are not an appreciable factor in producing unsatisfactory economic conditions in these complaining Massachusetts communities. In some Massachusetts communities, however, a factor in producing unsatisfactory economic conditions can be found to be the result of a failure on the part of our people and their legislators to discriminate between proper and improper subjects for the exercise of governmental powers in the way of legislation and taxation.

If the people and industries of Massachusetts are not the most heavily taxed of any State in the Union, as has been claimed, the State certainly stands among the first in this respect. The taxes collected in Massachusetts by State authority alone have increased from \$85,818,000 in 1910 to \$198,116,000 in 1920. This is exclusive of the taxes collected under the authority of the United States Government, which raised the total furnished in taxation in 1920 by the people of Massachusetts to \$457,012,000, or practically half a billion dollars. The people of Massachusetts paid in 1920 three and a half million dollars interest on a State debt which has been incurred in various justifiable and unjustifiable expenditures for the supposed promotion of public welfare. Rich States like New Jersey and Pennsylvania, with which Massachusetts must compete industrially, have comparatively small recently created State debts.* The people of Massachusetts are paying more and more every year to support an ever-increasing army of city, county and State officials or employees to promote their welfare.

*June 1, 1922, the State debt of New Jersey was \$17,116,000 and that of Pennsylvania was \$43,878,572. On December 1, 1921, the net State debt of Massachusetts was \$84,266,916.

Everybody contributes directly or indirectly to meet taxation and suffers in purchasing capacity in consequence thereof. This is why, when a man with some capital feels inclined to start a new enterprise in a Massachusetts community, he is likely to change his mind and invest his money in some other State where the risks to his investment from regulations and taxation seem less. A very large part of the taxes collected in this State are derived from the income from past savings of Massachusetts people which have been invested in enterprises elsewhere for this very reason.

What has been stated with respect to the futility of spending State funds in communities to improve a medical or health situation due to economic causes, applies equally to the expenditure for similar purposes of Red Cross funds, anti-tuberculosis society funds or funds of the Massachusetts Medical Society or any other private organization without in some way at the same time bringing about more satisfactory economic conditions.

There is an altogether too ready acceptance of claims of both official and non-official popular health or welfare organizations that decreases in infant mortality, in deaths from tuberculosis and other apparent improvements in health conditions are to be attributed to the activities of these agencies when such results are really due to improved economic conditions. Changes in economic conditions, lucrative employment, or unemployment, an increase or a decrease in the family purchasing capacity in a city, or a certain district of a city, is very quickly reflected in official statistics, as decreases or increases in morbidity and mortality. Other factors, of course, may enter to cause fluctuations in morbidity or mortality rates, but it is to be noted that both official and unofficial health agencies are usually silent with respect to their accomplishments except when morbidity or mortality is apparently decreasing.

SUMMARY.

We must realize that the problem of bringing about satisfactory rural medical care, which has been put up to the Massachusetts Medical Society, involves something more than devising new ways for a physician to give personal service to the public. The problem of proper medical care for rural communities in Massachusetts is fundamentally and chiefly an economic problem. In taking up this problem as it has, even to the extent of trying to point out a possible solution, the Massachusetts Medical Society is undertaking something which the Society was not designed to undertake.

The medical needs of these rural communities will not be satisfied by inducing competent physicians to practice in rural communities and by placing at the disposal of these physicians

and their patients such professional help and hospital facilities as members of the Society have it within their power to give. It is equally essential to the proper medical care of any community that provision be made for nursing service, for dental service, for health education, and in many instances for the means of securing household help or even a suitable diet. The money has got to come from somewhere to pay for these other essentials as well as to give a physician an income commensurate with the cost of a modern medical education. For reasons already stated it is believed that it is economically unsound and practically unwise to undertake to supply any of these essentials for proper medical care to a Massachusetts community unless the people who should be most directly interested—the people of the town, of a group of adjoining towns, of a part of a county or of a county—may be led to exhibit enough interest in their own welfare to undertake through local non-official civic organizations to so improve local economic conditions as to enable the people as a whole to provide and pay for their medical care, if at present without the resources to do so.

EMPHYEMA. REPORT OF ONE HUNDRED CASES.*

BY DONALD S. ADAMS, M.D., WORCESTER, MASS.

From the Surgical Service of Memorial Hospital.

A study of the hospital records shows 100 cases of emphyema from January, 1910, to January, 1920. There were 17 adults and 83 children. Of these 35 were females and 65 were males. Considering the age of the adult group, the youngest was 22, and the oldest 47, an average age of 30 years. Of those cases under 21 years of age the youngest was 3 months, and the oldest 18 years, an average of 5 years.

Ninety-seven of the 100 were frank empyemas and three were associated with lung abscess. A study of the predisposing factor or preëxisting illness revealed the fact that 94 had had pneumonia, three whooping cough and bronchopneumonia, and two of the lung abscess cases had inspired infected teeth during extraction under ether anæsthesia. One adult presented a metastatic origin.

Seventy-four cases were admitted with emphyema existing, and 26 developed the lesion on the medical side, having come in originally with pneumonia. The former group had been ill on the outside an average of 24 days, the longest 3 months, and the shortest 4 days, before being sent to the hospital.

Of the 97 frank empyemas the diagnosis was clinched in each case by the insertion of a

*Read before the Worcester District Medical Society, February 8, 1922.

needle. The lung abscess cases were diagnosed by the x-ray findings, history, physical findings, evidence of purulent expectoration, and in one case at autopsy. The treatment in all cases was operative.

It is of interest to note that, considering the entire group, 45% were operated upon within 24 hours after discovery of pus; 22% within 48 hours; 20% within 72 hours; 5% within 4 days; 8% within 10 days.

The last group were all adults and all made good recoveries. In those 26 cases that developed empyema under the care of our own staff, the average time between the discovery of pus and surgical interference was two days, the longest time was 5 days and the shortest was 24 hours. And again considering the 100 cases as a group, the average time between admission and operation was 6 days, the longest 29 days (one of the lung abscess cases) and the shortest time 24 hours.

In this series the lesion was equally divided between the two sides of the chest. Adult: Left 8, Right 9. Child: Left 44, Right 39.

Drainage was attained by either resection of rib or simple thoracotomy, there being a preponderance of the more radical procedure. Adult: Resection 10, Thoracotomy 7. Child: Resection 74, Thoracotomy 9.

Drainage was maintained by rubber tubes 82 times and by rubber spool 18 times. Post-operative irrigation of the chest was done in 28 of the 100 cases.

The following methods of securing anaesthesia were employed:

Ether, adult 7; child 54. Chloroform, adult 1; child 12. Local, adult 7; child 5. Ethyl chloride spray, adult 0; child 7. Chloroform and Ether, adult 2; child 5.

It is of interest in passing to note that the inadequate method of spraying with ethyl chloride was done 7 times, needless to say all in children. All were rib resections, all desperate cases, and all recovered.

Cultures of the pus either obtained at the time the chest was tapped or at the operation were reported in 92 of the cases:

(1) No growth, adult 2; child 2. (2) Streptococcus, adult 3; child 22. (3) Streptococcus and Staphylococcus, adult 0; child 1. (4) Pneumococcus, adult 4; child 41. (5) Diphtheroid, adult 1; child 0. (6) Staphylococcus, adult 3; child 7. (7) Pneumococcus and Streptococcus, adult 0; child 5. (8) Pneumococcus, Staphylococcus, Streptococcus, adult 0; child 1.

The average time of patients in hospital from time of admission to discharge was 45 days; from time of operation to time of discharge, 43 days. The longest stay was 240 days and the shortest 1 day.

From a clinical standpoint the leucocyte counts were interesting. Fortunately they were recorded in each case. The highest count noted was 66,000; the lowest 7,000, an average of

26,000. The point of greatest interest here, however, was the fact that in the patients that died, with one exception, in each instance the count was either above 40,000 or below 10,000.

The following complications were noted, all among children:

Scarlatina...2 cases.

Multiple abscesses of thighs and arms...2 cases. In one of them, a true septicæmic form, the same organism was found as originally taken from pleural cavity. In the other case a different organism was grown. Both patients recovered.

Diphtheria...2 cases.

Pneumonia developing on opposite side but undergoing satisfactory resolution...2 cases.

Double otitis media...1 case.

Osteomyelitis of ribs at operative site...1 case.

Acute nephritis...1 case.

Two cases of Empyema Necessitatis were noted in this series. Both children, two and five years of age; type of infection, streptococcus. They made satisfactory recoveries.

Twenty-four deaths noted in this series, all among children. Actual mortality 24%, child mortality 28.6%. The average age of the children that died was three years, the youngest four months, and the oldest ten years. Eleven of these were two years of age or under. Considering the total mortality the following facts were ascertained:

Type of operation: Resection 21, Thoracotomy 3.

Bacteriology: Streptococcus 10, Pneumococcus 9, Staphylococcus 1, Streptococcus and Staphylococcus 1.

Admitted with empyema: 20.

Developed empyema in hospital: 4.

Anaesthesia: Ether 15, Chloroform 4, Local 3, Chloroform-Ether 2.

Irrigated: 4.

Not irrigated: 20.

Operated within twenty-four hours after admission: 12.

Number admitted in moribund condition: 8. But three postmortem findings can be recorded:

(1) Empyema and acute purulent pericarditis. Streptococci septicæmia.

(2) Empyema and abscess of lung on same side. Staphylococci septicæmia.

(3) Empyema and diffuse lobar pneumonia on opposite side. Pneumococci septicæmia.

Follow-ups obtained through letter or examining the patient personally: Children discharged alive, 59. Children accounted for, 20. Of these fourteen are alive and ten dead. Of the fourteen alive twelve were rib resections and two thoracotomies. Rib resections, 12 (alive and well at present time). Scoliosis and retraction, 2. Reoperation for rib necrosis, 1. Recurrence of pus at end of five years—same culture, 1. Well over period of six to eight years with-

out subsequent trouble. 8; Thoracotomies, 2 (alive and well at present time).

Of the six patients that are dead, two died within six weeks after discharge. These patients went out against advice and probably had poor care. One resection and one thoracotomy died of influenza. Two resections died of pneumonia five years after operation.

Adults discharged alive, 17. Adults accounted for, 12. One lung abscess case died one month after discharge. The other reports good health at the end of six years. Thoracotomies well over a period of two years, 3. Resections well over a period of six to nine years, 6. Resection died of bilateral lung tuberculosis, 1.

Again let us consider the entire group from an etiological standpoint. Ninety-seven per cent. were associated with pneumonia. Two lung abscess cases were found autemortem and one postmortem. Considering these in addition to an acute empyema following closely a pelvic abscess which was definitely a case of metastatic or blood-borne origin, we can see the relation to the etiological factors as enumerated by Wilensky¹.

(a.) Meta- or post-pneumonic.

(b.) Continuity from a neighboring perforating abscess, especially a lung abscess.

(c.) Metastases from a distant focus of infection. The first group he considers the commonest, which our series seems to substantiate.

The use of the needle was the means of arriving at a diagnosis in all of the frank cases. As Ladd and Cutler² point out, the needle is the dependable diagnostician. Morris,³ in discussing the exploratory puncture, shows that a massive pneumonia will very often simulate fluid in the pleural cavity. The tap will many times be dry, or if a drop of pus or fluid be gotten, the microscopic findings will be helpful in differentiation.

Operation was performed after discovery of pus in ninety-two per cent. of the cases within a period of four days. The remaining eight per cent. went as long as ten days before other means than simple aspiration were resorted to. This group was all adults and all recovered. When we consider this, together with the fact that one-half of the group of children that failed to recover were operated upon within twenty-four hours, we are more than convinced that early radical relief is unwise.

The average time in the hospital was forty-five days. From time of operation to time of discharge forty-three days, the type of operation having little apparent effect on the number of patient's hospital days. Diezlerich as quoted by Wynne⁴ reports forty postoperative days. The white blood counts presented a significant picture, in all probability merely coincidental. Apparently a very high leucocytosis, as well as a low one, meant one and the same thing, for it foretold a fatal issue in nearly every case. In

Wynne's⁴ series the highest count was 28,000, the lowest 7,000 and the average 17,000.

The complications offer nothing unusual. In fact they were few in number and in no case fatal. Morrison⁵ reports a case of empyema complicated by whooping cough with operation and recovery. Wilensky¹ gives a complete table of complications.

Our actual mortality in this series was 24%. The mortality among children 28.6%. As pointed out by Ladd and Cutler², as well as Hodge⁶, the age of the patient influences the mortality record. Thus the former noted 32% of deaths under two years of age, and 16% between the ages of two and twelve years. Nathan reported 78% mortality under two years and Dowd reported 25.6% between the ages of two and fourteen. Holt as quoted by Hodge⁶ noted 74% for first year, 59% for second year, and 13% for third year. According to our series: One year or under 55.5%, two years 45.8%, between two and fourteen years 21.8%, over fourteen no deaths. Thus, the younger the patient the greater the mortality.

The type of organism also influences the mortality. Holt noted 56% with pneumococcus, 79% with streptococcus and 50% with staphylococcus. Our group of cases showed pneumococcus 37.5% with streptococcus 41.1%, staphylococcus 4.1% and mixed infection 4.1%.

And lastly, the type of operation. All of our series received open treatment, but the more radical procedure gave the highest mortality—25%; thoracotomy resulted in 18.7%.

It is well to consider three things, as cited by Locke-Thomas and O'Hara⁷, before attempting to relieve a pyothorax. First the type of infection, second the general condition of the patient, and third the stage in convalescence. The patient with a broncho-pneumonia frequently shows effusion early in the course of the disease, and at a time when his general condition is poorest. Streptococci are usually found. Empyema is a later manifestation in lobar pneumonia, the patient having frequently reached a stage of early convalescence. The pneumococcus is the prevailing organism. Accepting these statements as facts, it is fair to assume that they are to be handled differently. The effusion containing streptococci is usually merely turbid at first, which indicates aspiration and contraindicates more radical measures. When frank pus finally appears and the physical as well as the clinical signs indicate underlying consolidations, together with a very ill patient, simple aspirations should be continued until it is apparent the drainage is inadequate or, as occurred in two of our recent cases, the formation of multiple abscesses and sinuses marking the point of insertion, an infection from within out, as evidenced by culture. It is then that the next least radical step should be tried, either the insertion of a catheter or simple thoracotomy. The patient with a pleura

infected by the pneumococcus or staphylococcus is usually found not to be suffering from an underlying pneumonia but from the toxic and pressure effects of an undrained cavity. This patient is benefited by an immediate catheter insertion or thoracotomy. The same may be said concerning a late streptococci process under which the lung condition has subsided.

This paper does not intend to argue in favor of either the closed or open method of treatment. The individual case must be studied and the operation chosen that will best meet the issue. For, after all, the object is the same,—to obtain drainage as completely as possible with the least taxation on the patient's physical resources and restore a sound chest in the shortest period of time.

No doubt a number of cases are cured by repeated aspirations alone. Stone reports 11% of three hundred and ten cases so cured, while Wynne succeeded in clearing up 3.5% by this least radical of all procedures. The closed method of treatment is applicable to the streptococci type of case. Especially is it of value in the desperate cases where both sides have to be drained simultaneously, as cited by Mozingo.⁸ The operation of choice, however, is simple thoracotomy with or without a valve flap. We should well agree with Hodge, who points out that rib resection should be saved for those cases that do not clear up with less radical means; where adhesions must be freed, or to clean up old sinuses and necrotic ribs.

But two forms of anaesthesia should be considered for these patients,—novocaine infiltration or gas-oxygen.

Whether one uses sterile water, saline, boric acid or, best of all, Dakin's solution as a form of irrigation, the results are more satisfactory than if the cavity is allowed to empty by overflow or lung expansion. One has only to see the clean wound of the former beside the soiled wound of the latter to convince himself. Whether one has the benefit of a perfectly titrated hypochlorite solution or must rely on that made up from the commercial product, in either case Dakin's solution should be the choice. Nothing has been suggested that so quickly liquefies necrotic tissue, and lessens toxic absorption. In our series twenty-four cases were chosen that recovered and of these twenty-one were irrigated while three were not. In choosing twenty-four cases that did not recover it was found that nineteen were not irrigated and five were. Thus the mortality of irrigated cases was 14%, whereas the unirrigated mortality was over 30%. It is fair to assume then, that the cleansing of the parts had something to do with the ultimate outcome.

And finally, let us not lose sight of the after-care. Proper diet, fresh air and sunshine mean a great deal. The blowing of bottles, soap bubbles, or inflatable toys, have their beneficial effect on lung expansion. The surgeon who insti-

gates the coöperation of the pediatrician or internist will be amply repaid by their judgment on the state of the underlying lung and by their suggestions during the postoperative stage.

COMPARATIVE LUMINAL, BROMIDE, DIET, AND ELIMINATIVE TREATMENT OF EPILEPSY.

BY BUELL L. ASHMORE, M.D., NORTH GRAFTON, MASS.,

Assistant Physician, Grafton State Hospital.

THERE is much to be found in literature relative to the treatment of epilepsy. The individual so afflicted is severely handicapped for many reasons which are readily understood by those giving the subject consideration. He is generally considered to be in a class by himself in regard to associations, employment, treatment, and prognosis.

A group of fifty male patients varying in age from 19 years to 66 years, with an average age of 41.1 years, and duration of epilepsy ranging from three and one-half years to fifty-eight years preceding treatment, with an average of twenty years during which seizures have taken place in the thirty-seven cases, having reference in records to the time when seizures were first noted, was placed in the infirmary ward of the Grafton State Hospital, and drug and diet treatments were administered for six months, as follows:

GROUP 1. Ten patients received luminal or phenyl-ethyl-barbituric acid, grains one and one-half twice daily for three days, and then grains one and one-half *once* daily for the remainder of the time with laxatives or cathartics, other than magnesium sulphate, as necessary.

GROUP 2. Ten patients received luminal, same dosage as above, with magnesium sulphate, one ounce, twice weekly.

GROUP 3. Ten patients received triple bromide, grains fifteen (sodium bromide, gr. five, potassium bromide, gr. five, and ammonium bromide, gr. five) daily with laxatives or cathartics, other than magnesium sulphate, as necessary.

GROUP 4. Ten patients received triple bromide, same dosage as above, but with magnesium sulphate, one ounce, twice weekly as cathartic.

GROUP 5. Ten patients were kept on a regulated diet with laxatives or cathartics as necessary.

Many of the above patients, before treatment was begun, had been receiving infirmity care, as it was considered advisable, due to their mental or physical condition, or both.

It will be readily understood that the cases have been derived from among those of the more severely afflicted with the syndrome which goes to make up the condition termed epilepsy, as well as being a group of more nearly middle-aged patients.

During a period of twelve months, beginning April 17, 1921, including three months preceding and three months succeeding treatment, 2,502 seizures were recorded, with an average of 4.17 seizures of all types per month for each patient. The total number of seizures per month for each group was tabulated as follows:

In Group 1. April 17th to 30th, 1921, 60; May, 176; June, 91; July, 51; August, 63; September, 80; October, 68; November, 66; December, 46; January (1922), 26; February, 30; March, 18; April 1st to 17th, 18.

In Group 2. April 17th to 30th, 1921, 49; May, 72; June, 56; July, 35; August, 40; September, 56; October, 29; November, 28; December, 33; January (1922), 32; February, 33; March, 31; April 1st to 17th, 25.

In Group 3. April 17th to 30th, 1921, 22; May, 48; June, 44; July, 39; August, 31; September, 31; October, 25; November, 21; December, 21; January (1922), 28; February, 19; March, 21; April 1st to 17th, 10.

In Group 4. April 17th to 30th, 1921, 32; May, 61; June, 43; July, 54; August, 37; September, 31; October, 34; November, 40; December, 23; January (1922), 28; February, 19; March, 21; April 1st to 17th, 10.

Group 5. In this last group they received a regulated diet of food material as outlined per capita, forming the usual balanced ration. In addition to this, elimination was afforded by the use of laxatives or cathartics when necessary. The total seizures per month recorded for this group were as follows:

April 17th to 30th, 1921, 22; May, 42; June, 32; July, 22; August, 37; September, 33; October, 33; November, 30; December, 41; January (1922), 27; February, 32; March, 24; April 1st to 17th, 3.

Using the three months' record of seizures previous to treatment as a starting point, it was found that the seizures varied as follows on a percentage basis:

GROUP 1: 351 seizures. The treatment period of six months, 361 seizures, or 50.14%. Post-treatment observation period of three months, 81 seizures, or 23%.

GROUP 2: 201 seizures. Period of treatment,

207 seizures, or 51.49%. Post-treatment period, 111 seizures, or 55.2%.

GROUP 3: 133 seizures. Period of treatment, 178 seizures, or 67.4%. Observation period, 88 seizures, or 66.16%.

GROUP 4: 156 seizures. Period of treatment, 213 seizures, or 68.26%. Post-treatment period, 64 seizures, or 41%.

GROUP 5: 102 seizures. Period of treatment, 199 seizures, or 97.5%. Post-treatment period, 77 seizures, or 75.5%.

All groups showed a few pounds gain in weight, except Group 4, in which there was a shortage of five pounds for the group.

Age of onset was given as infancy in two cases; childhood in three cases; two to five years in five cases; five to ten years in four cases; ten to seventeen years in ten cases; seventeen to twenty-five years in five cases; twenty-five to thirty years in two cases; thirty to forty years in three cases; forty to fifty years in four cases; fifty to sixty years in one case. The remainder were unknown or indefinite.

ETIOLOGICAL FACTORS.

Eating cherries, 1; measles, 1; whooping cough, 1; typhoid fever, 1; alcohol, 4. In the organic group, head injury was given as cause of three cases, and four cases hemiplegic. In eleven cases the patient was primarily mentally deficient; history of epilepsy in the family in six cases, insanity in three cases. One case of mental deficiency in family. Other cases unknown or indefinite. There are two diagnoses of epileptic psychosis, clouded states, while the remainder are given as epilepsy with deterioration.

Luminal Case Report. C. H., a negro, male, age 36 years, with history of grand mal attacks of epilepsy since seven years of age, of Group 2, appeared to take the treatment fairly well, with a lessened number of seizures, and some indications of drowsiness, with no complaints of ill feeling, was found, forty-one days after treatment was instituted, to have an eruption on the skin which was more pronounced on face, neck and upper extremities, after which luminal treatment was discontinued. Temperature the next day was 99.6°, pulse 82, respiration 20. This eruption, which resembled that of measles at first, was discrete and papular, surrounded by reddish areola and rather firm, spread over the entire body, and during the next few days it receded and disappeared. Also, the temperature became normal, and it was noted that he was in an improved condition. The eruption began to recur about fourteen days following the first appearance. There was evidently itching, though as a result of patient's limited mental capacity, little definite information could be obtained subjectively. The eyelids became edematous and conjunctivitis developed. The mucous membranes of the mouth and throat were

reddened, tonsils became swollen; the tongue presented a dry appearance, somewhat swollen, and acute bronchitis symptoms were present. There was no diarrhoea or localized tenderness in abdomen. The urine was highly colored, with acid reaction, specific gravity 1.020, trace of albumen, no sugar. Microscopic examination of urinary sediment revealed a few red blood cells and leucocytes, besides many epithelial cells and a few granular casts. The temperature never went higher than 102.6°, nor pulse over 124. The respirations were generally around 20 and 30 at the greatest. The condition became worse. The spots which were at first separated, more noticeably on the trunk, became confluent. The eruption afterwards took the form of a desquamating eczema, and later had a tendency to ulcerations, with pustular formation. Patient died twenty-seven days after first appearance of symptoms.

Bromide Case Report. Case of P. D., of Group 3. A white male, 59 years of age, with history of grand mal attacks of epilepsy of an indefinite duration, and who has been a patient in hospital during the last six years; fairly good physical condition; mentally deteriorated. He declined rapidly during treatment. There was evidence of motor depressant effect as well as lessening of activity of intellectual centers. Heart action affected. There was greater tendency to coldness of extremities, and treatment was discontinued at the end of fifteen days.

Diet Case. Case of A. J., of Group 5. Died during a seizure shortly after treatment was completed, and before observation time had expired.

Bromide Case. Two cases, A. G., and F. W., of Group 3. Unreliable, as seizures had been rarely noted, and there was none recorded during the entire time.

Luminal Idiopathic Case. Case of A. P., of Group 1. Was especially happy, and so he expressed it during treatment. He felt sure he was much improved, and wrote in glowing terms of the treatment which he was receiving. The seizures were fewer in number, he gained in weight, and general condition improved. He was more inclined to be helpful when possible. When treatment was discontinued, the seizures became more severe, his mental condition became more disturbed, making it necessary to remove him from the infirmary to a more suitable ward. This tendency is noted, to a lesser degree, in a number of other patients following luminal treatment.

Some of the luminal treatment patients appeared depressed and less inclined to mental or physical exertion, which also occurred in a case of bromide administration. In other cases of patients who were delusional or hallucinated the symptoms were enhanced, though it was generally recognized that as a whole the patients did not exhibit disturbed mental states to the degree

which occurred previous to treatment. The tendency to violence was not so great.

Bromide cases continued much the same during the post-treatment period as during the treatment period in regard to drug effect. Bromism was found in the greater number of patients following treatment, and in a few cases dementia, which was present at the beginning of treatment, either increased or a condition was produced which closely resembled it.

According to Grinker, *Journal A. M. A.*, August 28, 1920, he has tested one hundred cases of epilepsy with luminal, and some of his cases have been free from attacks for a period of from three to four years, others from one to two years, and still others, who constitute the large majority of cases, for a number of months. According to a recent communication from him, another article is to appear soon in regard to further experiences with luminal in epilepsy.

CONCLUSIONS.

Luminal has a place as a therapeutic measure in the treatment of the epilepsies, and when taken in the doses used, does not produce the mental torpor manifestations which occur in the case of administration of bromides, and in many cases it is more beneficial; yet, it should be used with greater care and with selective cases, because of toxic effects which may be attributed to it. Neither drug appears to be habit-forming.

In cases of both luminal and the bromides, active treatment periods completed, the seizures were more nearly controlled with the former drug. From the standpoint of numbers and oftentimes in regard to severity, cases of idiopathic origin were the more responsive. Diet and elimination treatment group obtains last place on the list, but are very important, either alone or in conjunction with other recognized methods of treatment. No particular laxative or cathartic appeared superior to others during this period, though in the post-treatment observation period Groups 1 and 4 contained the lowest percentage of seizures of the first four groups. Special care to avoid auto-intoxication in Group 5 played a very important rôle in the reduction of seizures obtained there. Beneficial effects were noted in all groups during post-treatment observation period.

FIBROMA AND SARCOMA OF THE OVARY. REPORT OF TWO UNUSUAL OVARIAN TUMORS.

BY JOE VINCENT MEIGS, M.D., BOSTON.

THIS paper is written for the purpose of reporting two unusual ovarian tumors removed from patients at the Free Hospital for Women in Brookline, Mass. The first case revealed a combination of fibroma and fibro-sarcoma in one

tumor, with small fibromata of the other ovary. The second case combined a fibroma and malignant papillary cyst-adenoma with a malignant papillary cyst-adenoma of the other ovary.

In the literature that has been reviewed for this paper there is no actual case reported of either of these types of mixed tumors of the ovary. Cullen²³ reported a case of carcino-sarcoma of the ovary, the sarcoma probably developing from the stroma of the adeno-carcinoma, although which was primary could not positively be determined. Forssner²² reported two cases of carcino-sarcoma of the ovary. Before presenting the two cases a brief résumé of the literature on fibroma and on sarcoma of the ovary will be given.

The origin of fibromata of the ovary is uncertain, according to Aschoff. The points of probable origin follow:—(1.) From an inflammatory exudate on the surface of the ovary. (2.) From a corpus albicans. (3.) From a corpus luteum. (4.) From the stroma of the ovary. (5.) From the capsule of the ovary.

Fibroma must develop from connective tissue and Hellman¹⁵ states that "connective tissue can be found in the stroma, corpus luteum, corpus fibrosa, in the organized blood clots and in the capsule." These tumors probably develop from one of the above sites; some from one site and some from another.

They grow in three forms: The diffuse, in which the whole ovary is involved; the circumscribed, in which only a portion of the ovary is involved; and the pedunculated type, which is very rare.

Fibromata of the ovary are not very common, although probably more so than most writers state, the usual estimate being that they form two per cent. of ovarian tumors. Howell, in "The American System of Surgery," states that they are not as rare as might be inferred from the literature. Martin-Jung-Schmitz²² states that "fibromata of the ovary are relatively frequent." Petersen,²⁴ writing in 1902, says that "the work of Doran-Briggs-Coe, and others, has shown conclusively that the disease, while rare, is common enough to necessitate consideration from the standpoint of diagnosis." He was, however, in 1902, able to collect only 82 cases in the American literature. Fullerton¹⁵ believes that pure fibromata are very rare. Clark and Gabe,⁶ whose article is the latest upon this subject, state that "ovarian fibromata are sufficiently rare to warrant the report of all carefully studied cases."

Fibromata of the ovary are not common in young people. They usually occur in women at about the time of the menopause.¹⁵ One case of a fibroma in a girl of 17 was considered unusual. Coe, however, considers them the product of youthful and active ovaries, not of senile. The age limits given are 17 to 72.²⁵

The symptoms are not definite, the most common being pain due to pressure from the tumor,

and ascites. If the tumor has reached a large size it may be noticeable to the patient as an increase in the size of the abdomen. Loss of weight is noticed in some cases, especially those with ascites. Coe⁷ reported the interesting case of a woman whose abdomen, at operation, was found to be full of fluid and was closed because a malignant tumor was thought to be present. The patient was tapped twice later, and finally was operated upon again, when a fibroma was removed. This patient had typical symptoms of malignancy, but was cured upon removal of a fibroma of the ovary. Numerous cases objectively show ascites, the percentages being from 5 per cent. (Hellman) to 40 per cent. (Petersen).

The tumors vary in size from 1 cm. or less to the size of a man's head or larger. They are usually freely movable and non-adherent. These tumors usually are unilateral, although bilateral fibromata may occur. Ascites is present in most of the cases, although it is not always present. The cause of this ascites is not known, and, as Coe⁷ says, "adhesions are rare and the tumors very slow growing and non-irritating. Therefore the question of ascites is a puzzle." Fullerton¹⁵ believes the presence of ascites is the reason for the non-adherence of these tumors. The cause of ascites is variously stated as follows: It may be due to a chemical action, to a mechanical, to a hyperemia, or to a secretion from a degenerating tumor.

The treatment is simple excision of the tumor and ovarian tissue. The prognosis is excellent, for probably very few of these tumors become sarcomatous. In fact, no definite case was found reported in the references studied.

Sarcoma of the ovary is said to be more common than fibroma, the percentage given being 5 per cent. of all ovarian tumors. These tumors originate, as do fibroma, from any of the areas of the ovary containing connective tissue. Reel²⁸ states that he found a specimen of sarcoma of the ovary which apparently took its origin from a tumor of this type (fibroma). This is the only suggestion of a case similar to Case No. 10026, reported below. Graves¹⁴ states that "sarcomata of the ovary are very rare tumors. They may originate as a malignant growth or they may represent a degeneration of a fibroma." Johnson¹⁶ feels "that fibromata of the ovary are more subject to malignant and other forms of degeneration than are fibroid tumors of the uterus." From these opinions it can be inferred that probably some of the fibro-sarcomata of spindle-cell type develop from a fibroma of the ovary. Case No. 10026 seems to be an incidence of this type of case in which the sarcoma in all probability developed from the fibroma. Most writers believe sarcoma of the ovary to be bilateral, and that ascites is a most usual occurrence.

There are two main types of sarcoma of the ovary which probably do not develop from the

same type cell. (Myxo-sarcoma, chondro-sarcoma, etc., are not considered in this paper.) One occurs in extreme youth, the other much later in life. In child life before the age of five 50 per cent. of all sarcoma of the ovary occur,³¹ and 50 per cent. of ovarian tumors before the age of five are sarcoma.¹⁹ These tumors are usually bilateral, soft, spongy, and of the round cell type of sarcoma. The type cell is not known. According to Ewing,³⁵ "it seems probable that some of the tumors with indifferent round cells are to be interpreted as one-sided developments of teratoma." Further, "the round cell sarcoma of the ovary is an ill-defined and rare form of malignant tumor which occurs chiefly in young subjects or children and proves rapidly fatal." They probably can be compared to the embryoma of the testicle. In adults the type of tumor is usually the hard, fibrous, fibro-sarcoma of the spindle-cell type. Porter³⁴ believes that "fibro-sarcoma of the ovary is less malignant than the other forms of sarcoma of the ovary." The two types are probably quite distinct and separate.

The treatment is hysterectomy with bilateral salpingo-oophorectomy, because this type of tumor is often bilateral, and also because it may metastasize to the uterus. The prognosis is not good.

The two cases reported below are interesting because they combine fibroma with two different types of tumors, a fibro-sarcoma in one, and a malignant papillary cyst-adenoma in the other. The opposite ovaries were involved in both cases, the first containing small fibromata, and the other a malignant papillary cyst-adenoma.

The two cases follow,—history, examination, operative findings, and pathological report. The stains used to prove the tumors actual fibromata were hematoxylin-eosin and Van Gieson's picro-fuchsin.

CASE 1.—13719-10026. Mrs. M. O., aged 53; children, one; miscarriages, two. Since October, 1921, the patient has noticed a mass in the left lower abdomen, accompanied at times by distention. This mass has not increased much in size, but there has been a loss of weight. The menopause occurred two years previously. In 1912 plastic operations were performed at the Free Hospital for Women.

January 12, 1922.—Examination reveals a movable tumor in the abdomen, and a question of fluid and malignancy.

January 19, 1922.—Operation by Dr. Graves: Supra-vaginal hysterectomy, midline incision. A large tumor is found, suggesting an ovarian cyst. Abdomen is full of blood-tinged fluid. No nodules are felt in the liver. Pedicle of the cyst of the left ovary is clamped and cyst removed, as well as the uterus with the other ovary and tube.

March 23, 1922.—Examination: Patient feels well and is gaining weight. Vaginal examina-

PATH. NO. 10026.—This photograph shows a small fibroma in the upper left-hand corner of the tumor mass. Its tissue is harder and more fibrous than the rest of the tumor, which is soft and friable. The tumor measures 15x12x12 cm.

tion shows slight resistance in the right side. No glands felt.

Macroscopical Examination: Specimen consists of a uterus with both tubes and ovaries. One tube and ovary separate. The left ovary is a tumor measuring 15x12x12 cm. This tumor consists of two parts, one a definite fibroma, which measures 3x3x4 cm., with two smaller tumors of the same type on its surface. The other part consists of soft, fibrous material that is of a fish flesh texture. At one end there has been some necrosis, and the tumor here is soft and bluish. The smaller part (fibroma) is not encapsulated. The tube is spread out over the surface of this tumor. The right tube and ovary are attached to the uterus. The tube is not remarkable. The ovary is covered with small nodules and measures 3x5x2 cm. Uterus contains multiple fibroids and measures 5x7 cm. Endometrium is 2 mm. thick, smooth except for one small polyp.

Microscopical Examination: The polyp is a polyp of the endometrium. The tubes are normal. Endometrium is atrophying. The piece of tissue from the probable fibroma of the ovary shows very compact connective tissue with but few nuclei. The cells and fibrils are very compact, with bundles which seem to run in many directions. There is a great preponderance of collagen fibrils. There are no mitotic figures to be seen. This tumor is a fibroma. Sections of the softer tumor show a tissue rich in nuclei and in nuclear figures. There are many mitoses present. There is not a thick deposit of connective tissue fibrils, and the nuclei are the most evident structure in the tumor. In one area there is seen the junction of the fibroma and the fibro-sarcoma. There is an abrupt change between the two types of tissue. A definite line

can be followed for the whole length of the section, and in no part is there confusion as to which is fibroma and which is sarcoma. There is no capsule seen, the two different tumors being intimately joined together but being totally different at their junction. The other ovary shows small areas of fibrous tissue, growing on the surface, that give the impression of small early fibromata, and are totally different from normal ovarian tissue.

Diagnosis: Endometrial polyp; atrophying endometrium; normal tubes, multiple leiomyoma of the uterus; small fibromata of the right ovary; fibroma of the left ovary; fibro-sarcoma of the left ovary.

CASE 2.—No. 13862-10210. Mrs. I. K., aged 55; children, five; miscarriages, none. For about ten years the patient has been aware of a slight tenderness on pressure in the left lower part of the abdomen. About two months ago this tenderness spread to the opposite side of the abdomen. Menopause occurred eight months previous to entry.

April 3, 1922.—Examination reveals a large, somewhat mobile, abdominal tumor; genital atrophy; and a lacerated cervix which is nearly taken up.

PATH. No. 10210.—Fibroma and malignant papillary cyst-adenoma of the ovary. This photograph shows a fibroma of the ovary being invaded by a malignant papillary cyst-adenoma. The tumor measures 21x14x10 cm.

April 5, 1922.—Operation by Dr. Graves: Supra-vaginal hysterectomy; appendectomy. Midline incision. A large, hard, white tumor of the right ovary is found, with small cystic masses on its anterior surface, which is adherent to the rectum, small intestines, and the surrounding tissues. On the left is an inky-blue colored cyst of the left ovary which is only slightly adherent. The uterus is small and

PATH. No. 10210.—This photograph shows the outside of the combined fibroma and malignant papillary cyst-adenoma

normal in appearance. Gall-bladder and kidneys feel normal. Adhesions were freed and a routine supra-vaginal hysterectomy performed.

Macroscopical Examination: Specimen consists of a uterus with both tubes and ovaries attached, and the appendix. The uterus measures 7x3x2.5 cm. The uterine cavity is 4 cm. long. Endometrium is 2 mm. thick. There is a small nodule in the posterior wall of the uterus at the junction of the fundus and the cervix. The right ovary presents a tumor which measures 21x14x10 cm. The tube is attached to the tumor and is spread out over its surface. The tumor is composed of a large, fibrous mass that is nearly divided by a growth of many small cystic masses filled with a clear fluid and containing masses of a papillary growth. The surface of the mass is covered with these small cystic growths, that seem everywhere to be invading the solid tumor. The other ovary is composed of a cyst, measuring 11x6x4 cm., which is filled with the same sort of material as is contained in the cysts of the other ovary. There is no solid fibrous tumor structure in this ovary. The left tube is a hydrosalpinx measuring 8x4 cm. In some areas in both tumors the papillary growth has grown outside the cysts and is spread over the surface of the main tumor, and in places is invading it. The appendix is 3 cm. long and appears to be normal.

Microscopical Examination: Atrophied endometrium. Normal appendix. The cystic tumor of the ovary is a malignant papillary cyst-adenoma. The epithelium in places is growing rapidly and numerous mitotic figures are present. In one slide the growth is seen invading the solid tumor. The epithelium is cuboidal and the cyst is of the serous type. The solid tumor is made up of fibrous tissue running in bands. There is a great quantity of collagen

PATH. NO. 9938.—This photograph shows a fibroma of the ovary with normal ovarian tissue spread over its upper surface. There are a few small follicular cysts in the ovarian tissue. The tumor measures 10x10x9 cm.

fibrils, and the nuclei are not numerous. In some areas the connective tissue is spread apart by edema. This tumor is a fibroma of the ovary. The small nodule found on the back of the uterus on section shows a great many gland structures and papillary projections. The epithelium in areas is cuboidal, and in other places it is heaped up. This tumor contains many mitotic figures and is probably a metastatic nodule from the malignant cyst.

Diagnosis: Atrophied endometrium; normal appendix; hydrosalpinx, bilateral; malignant papillary cyst-adenoma with epithelium of the serous type, bilateral; metastatic adeno-carcinoma; fibroma of the ovary.

A LIPOMA WEIGHING TWO AND ONE-HALF KILOGRAMS, TAKEN FROM THE INNER ASPECT OF THE RIGHT ARM.

BY A. DALE KIRK, M.D., WORCESTER STATE HOSPITAL.

THIS case, while perhaps not exactly an exceedingly rare one, and even though it did not present much difficulty in diagnosis, is nevertheless very interesting, and, it seems to me, well worth reporting, because of the unusual size of the tumor and its unusual location.

The patient, F. S., shown in the accompanying photograph, was admitted to the Worcester State Hospital, June 23, 1922. From him the following story was obtained. He is an old man, seventy-nine years of age, who about thirty years ago fell and sustained some injury to his shoulder. He did not know the exact nature of this injury, or if any bones were broken. About

Tumor after removal.

seven years ago a small lump appeared in the inner aspect of his arm. This small tumor did not bother him any, and he did not pay much attention to it. He went about his work as a contractor, and says that it did not bother him in any way. Its growth was very insidious, and he claims that it did not begin to grow rapidly until about two years ago, when he had to stop work, and then it began to get larger quite rapidly. All this time he has had this tumor under his arm, he claims that it has never bothered him, except as a mechanical hindrance, and he was not at all enthusiastic about having it removed.

Upon examination we find a large, oval-shaped mass, hanging from the inner surface of this man's arm. It was rather soft, and semi-fluctuating, so that when the patient told us that a doctor had previously removed fluid from it,

Roentgenogram of arm.

we were almost ready to believe him, and were trying to figure out how a man of his age could be possessed of a cyst under his arm; and if a cyst, from what did it originate? However, on closer examination the tumor was found not to be perfectly oval in shape, but to be somewhat lobulated. It did not seem to be adherent to the deeper structures below, and it was not adherent to the skin above, although when the tumor was moved the skin above it would become somewhat wrinkled. It was quite freely movable and could be moved about on his arm quite easily. It was not in the least infiltrated

Patient, showing tumor of right arm.

and the skin at its point of attachment could be almost approximated with that on the other side. To be absolutely sure, however, that it was not a malignant affair, an x-ray was taken of the arm to rule out the possibility of any involvement of the bone, which might have been excited by the old injury. We were fairly certain, however, that it could not be sarcomatous or carcinomatous, because of the consistency of the mass, and the fact that the patient was in such good general condition.

Having satisfied ourselves that this was benign, the differential diagnosis must rest between one of three things:

1. Lipoma.

In favor of this we have a large, oval, rather lobulated, semi-fluctuating mass, which grew very insidiously and has never caused the patient any pain, or even discomfort outside of the fact that being so large it became a mechanical hindrance to him. It was subcutaneous and not fastened tightly to the skin or to the deeper tissues beneath.

2. Fibroma of the soft type. (Fibroma Molle.)

There was nothing which could really enable us to rule this out—although if it were a fibroma we would be inclined to expect it to appear more suddenly than this tumor mass did. Also the fact that it was somewhat lobulated would be more in favor of a lipoma, but would not by any means rule out a fibroma.

3. Myxoma.

These generally occur as rounded tumor masses, and from the characteristics of the tumor itself I do not think it could be differentiated from either a fibroma or a lipoma. These tumors sometimes originate in the sheath of nerve trunks, and if this was the case this would be an excellent location to expect such a growth. All of these conditions were considered and before operation opinion was still divided as to whether it was a lipoma or a fibroma.

At operation the mass was easily enucleated by Dr. Curran, and the tumor shown in the accompanying photograph was removed. It was found to weigh 2.5 kilograms, and measured 28x19x11 centimeters. The pathological examination showed it to be a typical lipoma.

The patient's arm has rapidly healed up and he is now very much elated that he is free from this cumbersome mass.

A NEW METHOD FOR THE ESTIMATION OF PEPTIC ACTIVITY OF GASTRIC CONTENTS, SUITABLE TO CLINICAL APPLICATION.

BY C. W. MCCLURE, M.D., BOSTON, AND
P. L. E. SCHABACKER, BOSTON.

[From the Evans Memorial.]

THE present communication is the description of a practical method for the estimation of pep-

tic activity of gastric contents, conforming to the general principles of enzyme action as at present understood; and of the application of the method to the determination of peptic activity of the stomach contents of human beings.

Up to the present the determination of relative quantities (concentration) of pepsin in stomach contents, as ascertained by the estimation of peptic activity, has been of very little assistance in explaining gastrointestinal symptomatology. One of the several reasons for this lies in the fact that methods for estimating peptic activity in gastric contents have given such variable results that only most inaccurate knowledge of the concentration of pepsin present could be obtained. The variability in results is due to the fact that the methods have not conformed to the general principles resulting from the application of physical chemical concepts to enzyme action. Obviously, a method conforming to these principles is necessarily one of the first steps in determining whether possible abnormalities in peptic activity play a rôle in the production of gastrointestinal symptomatology, and this is the reason for the present study.

The reagents required and the technic of procedure of the new method are as follows:

Great care was exercised in the preparation of the buffer solution, as it was felt that the uniformity and purity of this factor determine in large measure the course of all enzymic digestions.

A stock solution of hydrochloric acid was prepared by distilling a 20 per cent. pure acid in quartz, collecting the middle third of the middle third, and diluting the distillate to the desired strength (about half normal) with freshly distilled carbon dioxide free water. The strength of the acid was determined by exact gravimetric analysis as silver chloride.

Sodium hydroxide was prepared free from carbonate in a manner recently described,¹ and which may be summarized as follows: Forty-five grams of initially very poor sodium hydroxide were dissolved in 500 c.c. of freshly distilled water, the carbonate content determined by titration at 0° C., precipitated as carbonate with an excess of pure barium hydroxide, and the excess of the latter, after careful gravimetric analysis, removed as the sulphate with the calculated amount of pure sodium sulphate. The strength of the alkali was determined by titrating with the acid as described above, using weight-burettes and methyl red as the indicator. It was stored in paraffin-lined bottles and protected against carbon dioxide contamination by a soda lime tower.

Crystallized citric acid of the highest purity was next dissolved in carbon dioxide free water, the resulting solution being slightly in excess of half molar. Exact analyses of its strength were made with the sodium hydroxide described above, again using a weight-burette for the lat-

ter. Into a one-liter graduated flask was measured exactly enough of the citric acid to give 52.52 grams of the original solid. To this was added by weight enough of the sodium hydroxide to produce two-thirds neutralization of the acid. The volume was then made up to one liter, giving a fourth molar solution. This was used as the stock solution, keeping it in a paraffin-lined bottle and diluting with carbon dioxide free water to the final concentration of M/16 disodium monohydrogen citrate. To all solutions containing the sodium citrate thymol crystals were added to prevent the growth of molds.

N/10 HCl is made by diluting the acid described in the foregoing section to proper concentration, and titrating the strength with the standard NaOH also described, using weighing burettes and methyl red as the indicator.

The sodium citrate-hydrochloric acid mixture is prepared by pipetting 300 c.c. of the M/16 sodium citrate solution into a liter volumetric flask, rinsed with N/O HCl, and making up to the mark with N/10 HCl.

Edestin solution: One (1) gram of edestin,* weighed within an accuracy of 1 per cent., is placed in a mortar. The edestin powder is then titrated with a few c.c. of the sodium citrate-hydrochloric acid mixture to make a paste; by rapid trituration and slow addition of the sodium citrate-hydrochloric acid mixture the edestin powder can be kept in a finely divided state, which will allow it to go into solution readily. A total volume of 100 c.c. of the acid mixture is added from an ordinary graduated measuring cylinder. A small amount of residue will not dissolve, and is readily gotten rid of by centrifugalization and decantation of the supernatant fluid.

Twenty-five per cent. metaphosphoric acid solution: The preparations of metaphosphoric acid usually obtained in the market should be fused in a graphite mortar until the white fumes of phosphorus pentoxid begin to appear. The fused material can be cooled conveniently by pouring on a clean pie-pan floating on cold water. Metaphosphoric acid so fused will remain a potent protein precipitant if kept in tightly stoppered bottles.

The 25 per cent. solution can be made quickly by triturating the desired amount of metaphosphoric acid and water in a mortar.

Digestion mixture and Nessler's solution are prepared as directed by Folin and Wu,² the standard ammonium sulphate solution as directed by Folin and Denis.³

TECHNIC.

Centrifugalize or filter a small portion of the gastric contents and place one (1) c.c. of the clear fluid obtained in a 100 c.c. volumetric flask, then fill up to the mark with the sodium citrate-hydrochloric acid mixture.

*The edestin preparation was furnished through the courtesy of the Arlington Chemical Company, Yonkers, N. Y. The authors take pleasure in acknowledging indebtedness for their cooperation.

Pipette 9 c.c. of the 1 per cent. edestin solution into test tubes (100 mm. x 10 mm.) and place in a water bath at 40° C. for five minutes. Then add one (1) c.c. of the diluted gastric contents to each tube, shake and replace in the water bath for a period of 60 minutes. At the end of this time remove the tubes and immediately add 2 c.c. of the 25 per cent. metaphosphoric acid solution, shake violently, allow to stand 60 seconds and filter, using dry filter paper. The filtrate should be perfectly clear. One (1) c.c. of the filtrate is Kjeldahlable according to the micro-method of Folin and Wu,² in the following manner: To each of two of the large Pyrex tubes, recommended by Folin and Wu, one (1) c.c. of the filtrate is added. Then to one of the tubes one (1) c.c. of the sulphuric-phosphoric acid mixture is added and 2 c.c. to the other tube. Digestion is carried out as described by Folin and Wu.² In brief,⁴ this consists in boiling off the water and, when the white fumes of sulphuric acid begin to develop, the mouth of the tube is covered by inverting a small Erlenmeyer flask into its mouth. Digestion is continued for from 30 to 60 seconds after the last trace of brown color has disappeared. The tube is then allowed to cool for 60 to 70 seconds, from 5 to 10 c.c. of water are quickly added and the contents of the tube cooled. The contents of the tube, to which the 2 c.c. of the acid mixture were added, are transferred quantitatively to a 100 c.c. volumetric flask and the total volume made up to about 60 c.c. with water. Then 30 c.c. of Nessler's solution are added and the flask filled up to the mark with water. The nesslerized solution is centrifugalized to get rid of the sediment* and compared with standard ammonium sulphate solutions usually containing 0.25 and 0.5 mgm. nitrogen. These are prepared by placing 2 c.c. of the acid mixture in a 100 c.c. volumetric flask, adding 5 or 10 c.c. of standard ammonium sulphate solution containing 0.05 mgm. per c.c., about 60 c.c. of water, 30 c.c. of Nessler's solution and making up to the mark with water. If sufficient color does not develop in the flask containing the Kjeldahl filtrate, then the other tube is to be nesslerized. To this tube add water up to the 35 c.c. mark, 15 c.c. of Nessler's solution, and, if necessary, centrifugalize to get rid of any sediment. While this procedure practically doubles the work of experiment, it gives an elasticity to the method which experience has shown to be essential.

The total number of milligrams of nitrogen found in the filtrate, after the metaphosphoric acid precipitation, is taken as an index of peptic activity. Using this index, the peptic activity of gastric contents obtained from a small number of normal young men, has varied between 3.6 mgms. and 5 mgms. These gastric contents

*The sediment must be pure white and not discolored by the precipitation of any of the coloring matter.

were obtained an hour after the ingestion of the Ewald test-breakfast.

DISCUSSION.

Methods representative of those devised in the past for the estimation of the peptic activity of gastric contents may be divided into the following classes:

1. Those in which gastric contents act on a substratum in the form of a solid mass placed in them or in a dilute HCl solution to which gastric contents are added: To this class belong the methods of Mett and Grützner. The Mett method³ is the well-known one of measuring the lengths of coagulated egg albumin in capillary glass tubes, before and after placing them in a solution containing pepsin. In the method of Grützner⁵ pepsin is allowed to act on fibrin which has been infiltrated with carmin. The amount of carmin liberated is determined colorimetrically and is used as an index to peptic activity.

2. Those in which gastric contents act on a flocculent suspension of edestin, in dilute solution of HCl: The complete disappearance of the precipitate is taken as the end-point of digestion. To this class belong the methods of Farrington, Lewis and Brown,⁶ and of Brewster.⁷

3. Those in which gastric contents act on some protein dissolved in dilute HCl: In the method of Fuld,⁵ edestin is dissolved in diluted HCl, and mixed with an equal volume of gastric contents. The end-point of digestion is considered to be reached when ammonia, layered on top of the mixture, no longer gives a white ring. Gastric contents are added to the solution of an acid casein dissolved in dilute HCl, in the methods of Volhard⁸ and Gross.⁹ In the latter method the end-point of digestion is reached when no cloudiness is developed upon the addition of sodium acetate. In the method of Volhard the mixture of gastric contents and casein solution are incubated a specified length of time. Then the undigested casein is precipitated by the addition of sodium sulphate and filtered off. The filtrate is titrated with N/10 NaOH, against phenolphthalein, and the increased acidity is used to express the amount of peptic action which has occurred.

Schorer⁵ has developed a refractometric method for the estimation of the action of pepsin, and Northrup⁸ an electrical conductivity method. These methods are not practical for clinical use and will not be discussed.

In criticising such methods as those outlined, or in devising new methods which are clinically applicable to the estimation of enzymatic activities of fluids obtained from the gastrointestinal tract, it is important that certain factors be considered. These factors⁴ are (1) quantitative accuracy and practicability of procedures for estimating the amount of enzyme action; (2) uniformity of enzymatic activity; (3) proportionality of enzyme action; (4) stability of the

enzyme, and (5) the physical state of the medium in which the enzyme is to act.

Uniformity of enzyme action means that under a certain set of experimental conditions a given specimen of gastric contents will give the same results on repeated analyses. By proportionality is meant the relation existing between the amounts of material digested by varying quantities of gastric contents; *i.e.*, in the method here described 2 c.c. of the diluted gastric contents will digest one and one-half times as much edestin as will 1 c.c. of the same dilution. Stability of an enzyme is a term used to express the length of time an enzyme will remain active. The physical conditions under which an enzyme acts are important because in order to obtain uniformity of action the physical conditions must be constant. One essential reason for this is the fact that the size of the surface area of material exposed to enzyme action is a governing factor in the amount of the latter which will occur. Other factors are temperature, and the buffer conditions determining hydrogen ion concentration.⁹

In classes 1 and 2, under description of previous methods, the solid state of the protein to be acted upon allows for great variation in the surface areas of different preparations. In none of the three classes of methods was an attempt made to find hydrogen ion concentrations and buffer conditions which would bring about uniformity of enzyme action, nor was considered the effect of adding the gastric contents on the pH and buffer conditions of the medium in which the pepsin was to act. Furthermore, in most of the methods the technic used does not permit an accurate estimation of the end-point of digestion. From these remarks it is obvious that methods previously proposed for the estimation of peptic activity of gastric contents have not fulfilled the five conditions described above, observance of all of which are considered essential for a method whose use is designed to give information concerning relative quantities (concentration) of pepsin present in different specimens of gastric contents.

While devising the new method here described an attempt was made to find pH and buffer conditions which would give uniformity of peptic activity of gastric contents. During this attempt results were obtained which indicated that a sodium citrate-hydrochloric acid mixture modified the action of pepsin. Further investigation led to the mixture described under the technic of the method; and under the experimental conditions outlined uniformity of peptic activity is obtained. The proportionality obtained is 1:1.5; *i.e.*, 2 c.c. of diluted stomach contents will digest one and one-half times as much edestin as will 1 c.c. of the same dilution. Under the experimental conditions outlined it has been found that pepsin remains stable for a considerable number of hours. The physical condition of the edestin is that of a solution, so that the

factor of surface area is constant; and the possibility of disturbances in hydrogen ion and buffer conditions on the addition of the gastric contents has been obviated by sufficiently diluting the latter. This brief discussion shows that the new method is in harmony with the factors generally accepted as determining enzyme action, and which are considered essential for the estimation of enzymatic activity. Further, it is directly applicable to determining this factor in the gastric secretion, and permitting the possibility of an interpretation of results for physiologic or pathologic purposes. The procedure for digesting the filtrate, given in the description of the technic of the method, allows the determination of widely varying degrees of peptic activity. This makes easier the application of the method to the study of pathologic gastric physiology.

FRACTURE-DISLOCATIONS OF THE HUMERAL HEAD.

BY WELLER VAN HOOK, A.B., M.D., CHICAGO.

It is time for surgeons to recognize that a revolution has taken place in the open treatment of joint-injuries and diseases through the knowledge that subcutaneous fat-tissue can be excised from its seat, even without pedicles, and replanted successfully in injured joint-cavities. For this artifice makes it possible safely to leave in the joint-cavity bone surfaces not covered by periosteum or cartilage, and synovial membrane but covered by fat-tissue. Even defects of joint-capsules and ligaments result in minimal disturbance of function if the space is filled in with fatty connective tissue.

The mode of action, the meaning of this effect of fat transplantation needs a moment's thought for its full comprehension. Fat-tissue is areolar connective-tissue having a tendency to the storing of oil in the cell-bodies. This tissue has an abundance of lymphatic spaces and channels and a fair degree of vascularity. It is probably not exceeded in adaptability by any other tissue in the body. Everyone knows how easily the areolar tissue retracts when illness occurs, how the eye-ball stands out, the cheeks shrink, and wrinkles appear, and how, in certain diseases, such changes as those just mentioned become relatively permanent. A laborer, exhausted by a day's activity, shows

the lack of water in his tissues in the same way; next day he is himself again. After typhoid fever the areolar-tissue is emptied of the fat which was stored in the cell-bodies. Over-feeding for some weeks is required to restore the fullness. In the first case the lymphatic spaces and channels are more drawn upon, in the second case the cells themselves are deprived of their store of fat.

Again, when this tissue is subjected to recurrent pressure, as about the ischial region and back, it undergoes a sort of thickening or condensation. *Per contra*, the fat about the female mammary gland is soft and loose. So when areolar-tissue is transplanted, it must soon conform, in some degree, to the new physiologic local requirement. In joints, if subjected to recurrent pressure, it becomes thinner, tougher, and more resilient; and it loses much of its oil and lymph-space distention. It becomes resistant to traumatism, yet it retains much of its resilience.

J. B. Murphy thought that the transplanted fat-tissue became hygroscopic in character. But Lexer discredits the idea, with apparent justice, and shows how the transplanted tissue adapts itself to the new situation. He thinks that the fat-tissue, having undergone regressive changes, becomes vascularized in its new location by ingrowth of blood-vessels from the neighborhood, and that then a true but slight regeneration of fat-tissue can occur.

Moreover, by rapidly healing into gaps in other connective-tissue structures, transplanted fat-tissue prevents these structures from contracting adhesions to neighboring tissues, and leaves them free.

And this provision of surfacing tissue makes possible the growth of the endothelial cells lining the cavity over the engrafted structures, completing the capsule of the joint. Of course the foundation structure of the part is incomplete. Fat-tissue cannot replace wholly the lost bone, cartilage or fibrous connective tissue. The surgeon must bear this in mind and act accordingly. He must provide fibrous tissue and bone for support and muscle attachment where needed.

He who could successfully use this wonderful addition to our resources in joint-surgery must understand its principles and apply them. It is not to be forgotten that pedicled flaps, carrying with them their own blood and lymph supply, are superior to free flaps, for the latter cannot become as freely vascularized as the former. It is necessary to attach the flap where it is to grow, and the neighboring structures must not unduly interfere with it. And the joint must be dressed in such a position that relaxation is maintained until healing has occurred.

Then it must be remembered that functional management is most important. Massage and both passive and active motion are of supreme importance in gaining a functional success.

In carrying out this work dead spaces must be avoided, the distance between joint ends must be as small as possible. The most important structures are to be preserved (Lexer) and the re-establishment of muscular activity must be cared for.

The proper application of these general principles profoundly modifies all our previous conceptions of joint-surgery. Into other fields of their application we cannot now go; we are concerned with fracture-dislocation of the shoulder.

Fractures of the tuberosities of the humerus, whether extensive displacement has occurred or not, may well be treated as Speed¹ suggests, by open attack. The detached tuberosity may be held in place by a nail, screw or other mechanism. In such cases I would recommend raising a flap of areolar (fatty) connective-tissue from the side of the wound and suturing it to the capsule so that its body covers the bone-wound. Of course if the muscles could be attached otherwise to the humerus, the tuberosity could be sacrificed at once. Its value lies chiefly in supplying a point where the muscles can grasp the bone. If the small mass were removed, pedicled or free flaps of fatty connective-tissue would still need to be applied.

Where the whole head of the humerus has been broken off at the surgical neck, or separated at the epiphyseal line, or where a large part of the head is split off, healing takes place well enough if impaction has occurred, if reduction is effected or if aseptic re-attachment has been brought about by open operation. Incomplete reduction tends to much disability (Stimson's *Work on Fractures*).

But where dislocation of a comparatively small fragment, without muscle attachment, has occurred at the moment of fracture, the difficulty of replacement is usually great.

McBurney (*Annals of Surgery*) advised drilling a hole in the side of the loose body, and inserting into it a handled hook, which would give the operator a powerful grasp of the fragment that would enable him to draw the detached piece back into its place. In elderly, fat or feeble patients, the manipulations required may be so severe, so compromising to the neighboring structures that their desirability in opposition to the removal of the fragment may well come into question.

Tanton² reminds us of some of the older ideas as to treatment. He recalls the old, fabulous notion of letting the shaft unite to the fragment, and then reducing the dislocation with the aid of the shaft as a lever, the surgeon comfortably forgetting that, in the interim, the connective-tissues of the part would have suffered many deep-seated changes.

He recounts the method of Riberi, in which the head is left in its dislocated position, and effort is made, by early and prolonged mobilization, to produce a "humero-glenoidal anathrosis." Despite the fact that the method has

been followed by some successes it is not to be recommended, for obvious reasons.

And he mentions simple reduction, which, even when successful (as reported by Buchanan, Lambret and Hitzrot), does not seem to him to give results superior to that of excision of the small fragment. Indeed, Tanton, agreeing with Buchanan, regards excision as the method of choice. Sir Robert Jones seems to have been successful in reducing many cases with good functional results, using bloodless methods.

Hennequin and Loewy³ assert that intra-capsular fractures at the shoulder heal as well as extra-capsular, in opposition to the conditions at the hip. They state that full recovery of function cannot take place in them beyond middle age in less than six months or a year, if at all, unless reduction is complete.

On the other hand, J. B. Murphy⁴ has reported a brilliant result after nailing the small fragment in place.

Pool presented before the New York Surgical Association a woman, fifty years of age, upon whom he had performed an open reduction of a subglenoid dislocation, fracture having occurred at the anatomical neck. A practically perfect result followed. Tilton advocated attempts at reduction if there were periosteal attachments. Mathews found it impossible to reduce after three to five weeks, the glenoid seeming to be practically obliterated. Lilienthal had had four cases of fracture-dislocation with the best result in the case in which he was obliged to remove the head.

So there are not a few surgeons who prefer excision of the fragment, while some attempt closed reduction or effect bloody replacement and add some form of osteosynthesis.

This paper is written to contend that, with the use of a flap of fatty connective-tissue, the preference should be given to excision of the fragment, except in unusual cases, where reduction can easily be effected in comparatively young people or where the displacement of one of the tuberosities, with attached muscle, necessitates reattachment.

For what is to prevent the shaft of the humerus from resuming its function if properly brought into the empty glenoid cavity after the removal of the segregated head? It would be, I think, the filling and contraction of the glenoid in delayed cases, the shrinking of the capsule, and particularly the formation of adhesions about the denuded, fractured end of the humeral shaft. And, if operation is done early this need not occur.

The following case presents a cogent argument for the propriety of this choice of procedure.

A lady of fifty-two years, with medium skeletal development, fat, flabby and of pronounced sedentary habits, was struck by an automobile and thrown upon the right shoulder. I did not see her until four weeks later, when Dr. E. A. Doepp called me in consultation. The very imperfect x-ray picture showed a saucer-like piece

of bone knocked off the head of the humerus and lodged downward below the glenoid cavity. In view of the patient's condition, replacement with osteosynthesis seemed inadmissible; excision appeared necessary.

The joint was opened by an incision that separated the pectoralis muscle fibres, and the detached piece was removed. The upper end of the shaft entered the glenoid cavity without trouble. And the arm was dressed in a position of extreme abduction, after a large pedunculated flap of fatty-areolar tissue had been raised from the soft parts of the neighborhood, accurately pushed down through the joint cavity, and fastened with catgut in place between the injured humeral head and the glenoid cavity.

Recovery took place slowly, although wound healing was ideal. A very skilled masseuse kept up slight motion and promoted the general nutrition of the parts. But after several months, even a pronounced paresis of the deltoid, due to the original trauma, was overcome, and motion is now almost perfect at the shoulder-joint in every direction.

In this aseptic case the interposed flap of fatty tissue filled in empty spaces, hastened coagulation, and prevented all injurious adhesions.

Conclusions:

(1) Where wounds of the bony surfaces of any joint or of its capsule have occurred, and especially where loss of substance has taken place, fatty tissue (usually subcutaneous areolar tissue) should be implanted to cover the defect, whether or not the injured tissue lies between articulating surfaces.

(2) Since transplanted fat-tissue must become vascularized before it can be permanently stable in its new histological and functional relations, pedicled flaps are better, *ceteris paribus*, than free flaps which must acquire entirely new blood and lymph vascular associations.

(3) The removal of fragments of the humeral head, after simple fracture, gives excellent results under aseptic healing. But muscular attachments must be re-established, capsular rents and bone surfaces deprived of endothelium should be covered with transplanted fascia and fat, dressing should be maintained in full abduction, and massage and passive motion must be instituted and kept up until the maximum of function is restored.

CENTENARY OF LOUIS PASTEUR.

On the 18th of December, at Columbia University, in Havemeyer Hall, a large meeting was held to pay tribute to the memory of the Great Pasteur on the one hundredth anniversary of his birth.

The participating departments of the University were the College of Physicians and Surgeons, the Department of Romance Languages, and the Faculty of Pure Science, in cooperation with University Extension—the Institute of Arts and Sciences. Dean Woodbridge of the School of Pure Science presided.

Emmanuel de Margerie, of the University of Strasbourg, French exchange engineering professor, spoke briefly on "France's Estimate of Pasteur." He emphasized the fact that France revered Pasteur not only as a scientist but as a man. He showed that Pasteur was a man of a deeply religious nature, and that "Faith" was one great characteristic which permeated his thoughts and helped accomplish his deeds. He stated that about 36,000 out of 36,000 communes in France have honored the memory of Pasteur by giving his name to a street or an avenue. He said that a large percentage of the school children of France answered "Pasteur" to the question, "Who was the greatest son of France?"

Gary N. Calkins, professor of protozoology, next spoke on "The Debt of Biology to Pas-

teur." He referred to Pasteur as a "consummate master of the methods of science," applying the scientific method to both medicine and biology, though being neither doctor nor biologist. "The greatest expression of his genius was the Glorification of the Scientific Method." He pointed out that achievement comes not from reflected radiance of the palace of research, but from within. In showing how Pasteur's mind worked progressively, he pointed out that from the great end-results in preventive medicine one could look back to his work on rabies, on anthrax, on chicken cholera, or the silk-worm epidemic, on the activities of minute organisms, and on the discovery of the rotary power of crystals and molecular asymmetry. He showed how Pasteur shattered the old theory of fermentation and the still prevailing notion that small living beings, even as large as eels and lizards, were produced by "spontaneous generation." He emphasized the point that Pasteur laid down the great principles which were the basis of the modern technique in bacteriology and surgery.

Dr. Frederiek S. Lee, research professor of physiology, then spoke on "The Debt of Medicine to Pasteur." He referred to Pasteur as the revolutionizer of the science and practice of the healing art: as a dreamer who made realities of his dreams. He spoke particularly of his work on chicken cholera, anthrax and rabies, showing that Pasteur established three great principles:

1. That infectious diseases are caused by specific virus or organisms.
2. That the virus may be weakened by artificial means.
3. That the weakened virus may be used to protect against the stronger.

Dr. Lee had seen Pasteur in his great Rabies Clinic and spoke of him as "ever watchful, alert and sympathetic." Pasteur, he said, would accept no new fact except after repeated careful experiments; would arrive at no hasty conclusions, and was almost overconscientious in his carefulness. He vindicated, Dr. Lee said, the use of the laboratory as related to the bedside and the clinic. He waged constant warfare against "tradition not supported by facts," applying the method of proof by scientific experiment, the logical method of attacking all problems.

The one great lesson for a doctor to learn from the life of Pasteur is the dependence of true medicine on science and the methods of science.

Dr. Lee closed his address by turning to Professor de Margerie and declaring that the old friendship of France and the United States would ever be strengthened by the men of science in both countries who were following in the footsteps of the illustrious master, Pasteur.

TREATMENT OF MORPHINE ADDICTION.

We would not attempt to cure a consumptive of twenty years' standing in a few weeks, so why try to cure in haste a person whose system has been saturated with morphia, and who is suffering from as real a disease as the consumptive, writes Margaret Vivian, L.M.S.S.A., Lond., in the *Medical Press and Record*.

Most institutions for the cure of addicts either cut them off entirely and at once, or reduce their daily allowance so rapidly that much suffering is entailed, and they are discharged in a few weeks, almost sure to relapse.

The method used by this writer is much different and, as is logical, much more time consuming. Whatever the patient had been taking he is immediately reduced to two grains a day, on which dosage he can live comfortably. When he has become accustomed to this dosage he will eat and feel better. The daily dose is then reduced by one-quarter grain, each reduction remaining stationary until he has become accustomed to it. This is repeated until an allowance of one grain a day is reached, and eventually this is given at one time, in the morning, when it is most needed. From now on the reduction is carried out very slowly, one-half grain at a time, even if it takes 12 months to get rid of the last grain.

The hypodermic injection of emetine has been found a valuable ally. The writer used daily 3 doses of one-sixth grain each, reducing the dose after the first month or two.

 MEDICAL LITERATURE.

It is an awe-inspiring sensation, sometimes, as we sit upon the bank of the stream, to contemplate the flood of medical literature that pours past us like a mighty current, swollen and angry with the increasing burden of the spring freshets that are forced upon it. Where does it come from and whither does it go? Its sounds, we try to think, are in the distant hills of ideas and inspiration; its final resting places, we are forced to admit, are generally the dark cisterns of musty library filing shelves; cisterns always full but seldom drunk from. How often have we considered launching a frail bark on that mad torrent, but timidly withdraw, too conscious of the fate of the other flotsam that we see gliding past us. The bark that we would rather test on that strong course must be well framed and well timbered if we would have it live and tell its tale and carry cargoes.

There is a certain fascination about the printed word, especially if originally penned by oneself, and more especially if bearing the author's name, that is very subtle. We have all felt this hypnotic influence and struggled away from it or succumbed and produced, after great travail, an article, its main claim to distinction expressed by the candid phrase "a poor thing,

but mine own." We would advise any young author who contemplates throwing his chip upon the stream, either because he feels a message stirring within him, or for reasons of policy, to enter any large medical library and stand for a few moments,—like Clemenceau among the mastodons,—gazing upon those silent volumes in that great cemetery of ideas. If he is still eager then to searify white paper, let him get prayerfully to work. It may be that he can carve for himself a seat among the mighty and launch upon the world a new idea.

There are four types that usually deserve consideration. There are those that write but think not; there are those that think not and write not—and this abstinence deserves some credit; there are those that think but write not, and they form an intellectual and untried bulwark; and there are those honored few who think and give us their thoughts. Current medical literature is aptly named, for it comes through a stony channel and babbles as it flows, but it waters no gardens of the mind. It would be better for us all if its volume were reduced three-fourths, and so selected and directed as to irrigate the germs of ideas that lie dormant in our minds.

It is not a nihilistic text that we would preach, for the printing press is the greatest constructive engine in the world, but it must grind the wheat and not the chaff. If you have a message that must be delivered to the waiting multitude, no matter what the cost, then like Pheidippides of old, gird up your loins and make the effort; your achievement will be lasting and your memory honored.

 MEDICAL SCHOOL DORMITORIES.

"The Need for Dormitories at the Medical School" is the title of Dean Edsall's contribution to The Medical School Section of the Harvard Alumni Bulletin of December 7. The popular conception of the uses of students' dormitories has changed greatly in the last few years. Once considered of value for disciplinary reasons, because undergraduates could be herded together under the restraint of proctors, they have now, with the increasing country-wide difficulty of obtaining proper living quarters, become almost a necessity. The Medical School, as Dr. Edsall points out, is situated on the edge of a large city, somewhat remotely removed from desirable eating and lodging places. Many of the students come, unknown and friendless, from distant parts of the country and are forced to shift for themselves as best they can.

It is the theory among many older men, and men who are otherwise progressive, that what was good enough for them is good enough for the present generation. They are wrong in this, but their error lies in considering, or saying, that conditions which they were forced to meet

were good enough. One of the finer things about the present-day evolution of higher education is the interest and responsibility which the heads of our institutions are asserting towards their students as individuals. They are no longer regarded as impersonal beings who are to be crammed with as much technical knowledge as possible in a certain number of years, and then gotten rid of. Their hygiene, their physical well being, even their play are being regarded as factors in their lives to which we owe a duty. The students at the Medical School themselves, as evidenced by the report of a committee of their own number, feel the need of a dormitory and dining hall.

We are deeply interested in Dean Edsall's desire in this respect, and hope that the University may soon see its way clear to realize it.

CHILD HYGIENE.

Dr. Eugene R. Kelley, State Commissioner of Public Health of Massachusetts, in advising the Public Health Administration Section of the American Public Health Association at the Fifty-first Annual Meeting, in Cleveland, October 16, stressed the importance of a well-balanced nation-wide child hygiene program.

Dr. Kelley said, in part: "Two general methods of accomplishing the wide diffusion and application of public-health knowledge are naturally coming to the front. They may perhaps be designated as the autocratic and the democratic. One concept of how best to reach all our fellow citizens effectively with the life-lengthening, life-broadening and life-brightening message of modern hygiene is to prod them into routine utilization of its teachings; the other concept is to lead them to it, but to lead them faster than has ever been done before in the world's history."

MEASLES.

The Bulletin of the Chicago School of Sanitary Instruction, published by the Department of Health, issues a warning regarding the complacent way in which measles is being looked upon.

In the year 1920 nearly 10,000 children died of measles in this country. In 1921 120 deaths occurred in Chicago, and for the first ten months of this year 133 succumbed. Measles is distributed over the entire inhabitable globe from Iceland to Tierra del Fuego; when the Fiji Islands were invaded it was estimated that 20,000 deaths occurred in four months. In 1917 three states had a death rate of over 40 per hundred thousand from measles, and several of the large cities had even a higher rate.

News Notes.

PUBLICITY IN ILLINOIS.—The officers of Illinois State Medical Society have sent a letter to every physician in Illinois soliciting funds for the purpose of carrying on a lay publicity campaign through the newspapers of the state.

AWARD OF THE KNAPP MEDAL.—At the meeting of the Ophthalmic Section of the American Medical Association, Dr. Frederick H. Verhoeff, of Boston, was awarded the Knapp Medal for his paper on "Ghomas of the Optic Nerve." Dr. Verhoeff is president of the New England Ophthalmological Society.

DR. F. W. PEABODY, of Boston, professor of medicine at the Medical School of Harvard University, and physician-in-chief of the Boston City Hospital, has been elected a member of the Council on Pharmacy and Chemistry to fill the vacancy caused by the resignation of Dr. C. L. Alsberg, formerly chief of the Bureau of Chemistry, Department of Agriculture, and now director of the Food Research Institute of Stanford University.

DEATH RATE IN BOSTON.—During the week ending December 16, 1922, the number of deaths reported was 238, against 199 last year, with a rate of 16.25. There were 35 deaths under one year of age, against 24 last year. The number of cases of principal reportable diseases were: Diphtheria, 76; scarlet fever, 61; measles, 62; whooping cough, 90; typhoid fever, 2; tuberculosis, 31. Included in the above were the following cases of non-residents: Diphtheria, 9; scarlet fever, 11; measles, 1; whooping cough, 2; typhoid fever, 1; tuberculosis, 4. Total deaths from these diseases were: Diphtheria, 1; scarlet fever, 2; measles, 3; whooping cough, 4; tuberculosis, 15. Included in the above, were the following cases of non-residents: Diphtheria, 1; scarlet fever, 1; tuberculosis, 4.

BROOKLINE BOARD OF HEALTH BULLETIN.—This publication for December, in addition to the usual warnings about disease and advice regarding health rules, has a timely article on "Christmas Candy." The argument is submitted that since sugar alone only provides heat and energy and that other foods furnish these essentials, that the effect of candy is more likely to disturb digestion than to provide needed nourishment.

Further, that sweets can be eaten to much better advantage as found in fruits, and the claim is made that dates, figs and raisins are the most wholesome form of sweets for children.

Another article on school lunches presents a rational dietary for children.

THE HEALTH ADVISORY COMMITTEE OF THE RED CROSS.—This committee consists of Surgeon-General H. S. Cumming, Dr. George M. Piersol, Prof. C. E. A. Winslow, Dr. Livingston Farrand, Dr. John H. J. Uplam, Douglas Griener, Dr. Franklin Martin, Dr. William H. Welch and Dr. Herman M. Biggs. A meeting was held at headquarters this month for the purpose of formulating suggestions relating to health activities of the Red Cross.

MASSACHUSETTS GENERAL HOSPITAL.—A clinical meeting of the Out-Patient Staff was held in the Lower Out-Patient Amphitheatre Wednesday, December 20, 1922, at 12 noon.

Subjects discussed: Arthritis, Dr. R. B. Osgood; Arthritis, Dr. L. T. Swaim.

THE SECRETARY OF THE MASSACHUSETTS MEDICAL SOCIETY. Dr. BRIDGE, has moved to 182 Walnut Street, Brookline, near Village Square. To reach him telephone Brookline 0860 or take any electric car passing through Village Square, i.e., Boston & Worcester, Cypress Street, Chestnut Hill, Washington Street or Harvard Street.

Walnut Path, the first stop on Boylston Street, after Village Square, is opposite his house.

DR. HUBERT WORK'S SUGGESTION.—Dr. Work, retiring president of the A. M. A., has recommended dividing the Medical Profession in the United States into district medical organizations. At a banquet of the officers of the State Medical Societies comprising the Southern Medical Association this plan was opposed in the form of a series of resolutions.

DR. HOWARD A. KELLY'S EXPERIENCE WITH A SNAKE.—Last March Dr. Kelly was collecting snakes in Florida and was bitten on the end of an index finger by a cotton mouth moccasin about thirty inches long. Thinking that the snake had exhausted its supply of venom by biting itself three times, Dr. Kelly did not consider it necessary to make use of permanganate of potassium. He did not even place a ligature about the finger. Although the finger and hand became very swollen and there were enlarged axillary glands there was no constitutional disturbance. After the bite free hemorrhage occurred. The recovery of the finger was slightly incomplete after seven and a half months. The details of this experience are given in an article written by Dr. Kelly, which appeared in the *Therapeutic Gazette* under date of December 15, 1922.

WORCESTER DISTRICT MEDICAL SOCIETY.—The regular meeting of the Society was held at the G. A. R. Hall in Worcester, Dec. 13, 1922, at 4:15 P.M.

Dr. Walter D. Bierberbach of Worcester read an interesting paper on Kidney malformations and reported an interesting case of a unilateral fused kidney that had come under his observation. Dr. Philip H. Cook showed slides illustrating the value of Pyelography in the study of kidney malformations.

Dr. J. Dellinger Barney read a paper on the Operability of Prostatic Obstruction and discussed the problems as met in a large series of cases. Dr. Trowbridge showed a badly infected kidney which he had removed, with photographs of a large number of stones which were found in the kidney.

Dr. O. Draper Phelps in discussing the papers emphasized the value of drainage and said that in his experience the best anesthetic was gas oxygen. At the business meeting Dr. R. J. Shannahan, chairman of the committee appointed at the September meeting to consider the advisability of the society adopting the American Medical Association's Caduceus for the automobiles of the members, to take the place of the green cross that is now used by so many cults, reported that he had received 130 replies to requests for an expression of opinion as to the advisability of such action in favor of the adoption and four in the negative.

It was then voted to adopt the Caduceus and Dr. R. J. Ward was instructed to arrange to secure the emblems in quantity. The price will be \$1.20 if not less than 100 are ordered. All the members who wish to order them will please send their check for \$1.20 to Dr. Roy J. Ward at once, that the order may be placed as soon as possible. It was voted to pay the bills of the open meeting on cancer, amounting to sixty-three dollars.

DRS. G. N. COBB AND M. M. JORDAN have announced the removal of their offices to 21 High Street, Worcester, Mass.

THE GRADUATING EXERCISES OF THE JANUARY AND APRIL CLASSES OF WORCESTER CITY HOSPITAL TRAINING SCHOOL FOR NURSES were held Friday evening, Dec. 15, 1922. The January class consisted of Dorothy A. Freeman, Harriet E. Small, Elizabeth Corkum, Hazel M. Palmer, and Elizabeth M. Sheahan. The April class consisted of Mary E. Moore, Katherine J. Quirk, Mildred A. Stevens, Mary E. Garrity, Agnes M. Curley, Earl C. Marling, John F. Brazzill, Joseph G. Gaylord, Thomas A. Balboni, and Peter W. Babbitt.

CENTENARY OF LOUIS PASTEUR.—A meeting to commemorate the centenary of Louis Pasteur was held under the auspices of Columbia University Monday, December 18, in Havemeyer Hall, New York City. Speakers: Emmanuel de Margerie, D. ès S., of the University of Strasbourg; subject, France's Estimate of Pas-

teur. Gary N. Calkins, Ph.D., Professor of Protozoology; subject, The Debt of Biology to Pasteur. Frederic S. Lee, Ph.D., L.L.D., Research Professor of Physiology; subject, The Debt of Medicine to Pasteur.

INSULIN IN DIABETES MELLITUS.—At a meeting conducted by the New York Academy of Medicine on Dec. 21, 1922, Dr. F. G. Banting of the University of Toronto read a paper on Pancreatic Extract in Diabetes Mellitus. The paper was discussed by Frederick M. Allen and Henry R. Geyelin and Nellis B. Foster.

THE OPENING OF THE NEW BOSTON LYING-IN HOSPITAL.—The trustees, the medical staff and the Board of Lady Visitors of the Boston Lying-in Hospital issued invitations for the opening of the new hospital, 221 Longwood Avenue, corner of Avenue Louis Pasteur, on Wednesday, December the 27th, from 3 until 6 o'clock.

UNWELCOME GUESTS.—Chicago is trying to stir up interest in a rat-exterminating campaign, finding herself unwilling to play host any longer to a large house party which costs millions of dollars every year. Other cities are ridding themselves of these expensive pests, notably Boston, which has recently increased her rat-catching force.

DRY SWEEPING PROHIBITED.—New York has added a new regulation to her sanitary code prohibiting dry sweeping in any place or room where food or drink is prepared, cooked, mixed, baked, exposed, bottled, packed, handled, stored, manufactured, offered for sale, or sold.

BREAST FEEDING VS. BOTTLE FEEDING.—The Bulletin of the Chicago Department of Health points out that artificial feeding as practiced in typical city populations, among all classes, nationalities, and earnings groups, is attended by a mortality from three to four times as high as the mortality among breast-fed infants.

This situation lends itself ideally to correction by the practicing physician.

MEETING OF THE ESSEX SOUTH DISTRICT SOCIETY.

The Essex South District Society of the Massachusetts Medical Society held their regular meeting at the Beverly Hospital, Wednesday, December 13.

From six to seven there was inspection of the hospital followed by this program of short talks and demonstrations given by members of the staff:

6:00 and 6:15—Pathological Laboratory. (a) Easy Method of Staining Diphtheria Smear for quick Diagnosis. (b) The Importance of Differential White Count. Dr. Clifton Buck, Medical Staff, Beverly Hospital.

6:00 and 6:15—Doctors' Library. Middle Ear Disease and Mastoiditis in Malnutrition. Dr. Thomas Odeneal, Otolologist, Laryngologist and Ophthalmologist to Beverly Hospital.

6:30 and 6:45—Doctors' Library. Showing of cases. Dr. P. P. Pohnson, Surgeon in Chief, Beverly Hospital. Demonstration and talk. Dr. Isobel Bogan, Roentgenologist, Beverly Hospital, showed interesting X-rays between 6:00 and 7:00. Miss Pauline Smith, Occupational Aid, Beverly Hospital, demonstrated Occupational Therapy between 6:00 and 7:00.

Dinner was served at 7:00 p. m. after which the following program was enjoyed: Dr. F. W. Baldwin, president of the Essex South Society, presiding:

Address of welcome by Mr. John L. Saltonstall, president of the Board of Directors of the Hospital.

Address by Dr. John W. Bartol, president of the Massachusetts Medical Society.

Address by Dr. Walter Bowers, Managing Editor of the BOSTON MEDICAL AND SURGICAL JOURNAL.

A paper by Dr. Peer P. Johnson, Surgeon in Chief of the Hospital, entitled "Diagnosis of Gall-Bladder Disease." The points brought out in his paper were illustrated by showing of cases.

Dr. J. D. Adams, Boston, visiting Orthopedist of the Beverly Hospital, spoke on backache and other orthopedic problems.

About one hundred members were present. The following towns were represented: Boston, Lynn, Swampscott, Cliftondale, Salem, Beverly, Hamilton, Ipswich, Manchester, Danvers, Middleton, Hathorne and Essex.

The following local men hold these offices in the Society: President, Dr. F. W. Baldwin; Vice-President, Dr. J. A. Shatswell; Secretary, Dr. R. E. Stone; Councilors, Dr. P. P. Johnson and Dr. G. M. Cline.

—R. E. Stone, M.D., *Secretary*.

WILLIAM THOMPSON SEDGWICK MEMORIAL LECTURESHIP.

For the purpose of commemorating the services of William Thompson Sedgwick to the cause of Biology and Public Health there has been established a Memorial Lectureship in the department of the Institute of Technology which he created. The desire of the founders is that the Sedgwick Memorial Lectures shall be given from year to year by men of distinguished eminence in any one of the subjects comprehended within the general scope of Biology and Public Health in order that it may fittingly express the deep and broad sympathy of the man whom the Lectureship is designed to honor.

The committee in charge of the Lectureship

consists of: Samuel C. Prescott, Massachusetts Institute of Technology; Edwin O. Jordan, University of Chicago; George C. Whipple, Harvard University; Gary N. Calkins, Columbia University; Charles E. A. Winslow, Yale University.

The first William Thompson Sedgwick Memorial Lecture will be given in Huntington Hall, 491 Boylston Street, Boston, Mass., on Friday, December 29, at 5 o'clock, by Edmund Beecher Wilson, Ph.D., Sc.D., LL.D., M.D., Da Costa Professor of Zoology, Columbia University, on *The Physical Basis of Life*.

The public is cordially invited to attend.

MENTAL HYGIENE.

The Monthly Bulletin of the Massachusetts Society for Mental Hygiene for December reports that The Connecticut Valley Committee in Springfield has arranged an instruction or lecture course on "The Mental Hygiene of the School Child," which will consist of seven weekly lectures, to be given at the Springfield Academy of Medicine. The first of this series will commence on Wednesday, January 3.

"THE MENTAL HYGIENE OF THE SCHOOL CHILD."

Wednesday, January 3.—"What Is Mental Hygiene and Why Does It Concern Every One?" Dr. George K. Pratt, Medical Director, Massachusetts Society for Mental Hygiene, Boston.

Wednesday, January 10.—"Conduct Disorders in Children of the Pre-School Age." Dr. Douglas A. Thom, Director, State Division of Mental Hygiene; Chief of the Boston Habit Clinic.

Wednesday, January 17.—"Nervousness and Nervous Breakdowns in School Children." Dr. Abraham Myerson, Assistant Professor of Neurology, Tufts Medical School, and Consulting Neurologist of the Psychopathic Hospital, Boston.

Tuesday, January 23.—"The Backward Child." Dr. George E. McPherson, Superintendent, Belchertown State School for the Feeble-minded, Belchertown, Mass.

Tuesday, January 30.—"The Delinquent Child." Dr. Augusta Bronner, The Judge Baker Foundation, Boston.

Tuesday, February 6.—"The Mental Health of the High School Student." Dr. A. Warren Stearns, Assistant Professor of Neurology, Tufts Medical School, and Physician of Nervous and Mental Diseases, Boston Dispensary.

Wednesday, February 14.—"Education and Mental Hygiene." Dr. William H. Burnham, Professor of Pedagogy, Clark University.

The course tickets are obtainable from Miss Marjorie R. Latimer at Central High School,

Springfield, and will cost \$2.50. Single lecture tickets are 75 cents each.

A "Mental Health Week" was conducted in Fitchburg, to stimulate public interest in the establishment of a local branch of the Society and to focus attention on the new clinic secured for that place.

Speakers furnished by the Mental Hygiene Society addressed various civic organizations in Fitchburg such as the Rotary Club, Chamber of Commerce, the Women's Club, the Community League, and others on popular mental health topics. Some of the clergymen volunteered to make this subject the topic of a Sunday sermon, and generous press publicity was secured.

The concluding event of this "week" was a large public meeting on the evening of Friday, December 15th, at Wallace Auditorium. At this meeting the local branch organization was launched and announcement made of improved clinical service to care for early cases of mental disorder occurring either in children or adults.

This clinic was made possible through the cooperation and interest of Dr. Charles E. Thompson, Superintendent of the Gardner State Hospital and the new State Division of Mental Hygiene under Dr. Douglas A. Thom. Arrangements have been completed to have this clinic, which will be held regularly once a week, provide service not only to Fitchburg, but to the surrounding district as well. The clinic team will consist of a physician, a psychologist, and a social worker, all from the Gardner State Hospital.

CLINIC AT THE CHILDREN'S HOSPITAL.

The first Staff Clinic of the season was held at the Boston Children's Hospital on Friday afternoon, December 8th. Dr. Ober showed two cases, one of acute infectious arthritis of the hip, drained posteriorly with good function; the other a case of tuberculosis of the pubic bone extending outward to the hip. Dr. Anderson showed the x-rays of two babies each with diaphragmatic hernia. He spoke of the gurgling of gas in the bowel as the sign upon which the diagnosis was made in one case before the x-ray was taken.

Dr. Hill showed a child with purpura hemorrhagica on whom five transfusions had been done. The lack of blood platelets is supplied thereby but unfortunately the life of the platelets is only a few days.

Dr. Schloss showed very strikingly by x-ray plates the rapid deposit of calcium at the epiphyseal line as a result of the administration of cod-liver oil and exposure to ultra-violet light.

Dr. Osgood emphasized the great importance of safeguarding our milk supply to prevent

surgical tuberculosis in children. He spoke of the great frequency of tuberculous bone and joint disease in Edinburgh, where no attention was paid to bovine tuberculosis.

Dr. Cutler and Dr. Crothers showed a child with abscess of the frontal lobe of the brain, secondary to an injury received about six months before. The condition had been mistaken for anterior poliomyelitis and for tuberculous meningitis.

Dr. Stone showed a girl with bilateral hare lip but with a very small intermaxillary bone and with a flat nose due to defect of the nasal septum. The case resembled the so-called median hare lip.

Dr. Liebman spoke of the almost specific influence of the x-ray in the treatment of keloid but advised excision followed by x-ray exposures in the treatment of the extremely large keloid of the neck which he showed.

Dr. Mixer showed a case of retro-pharyngeal glandular tuberculosis associated with tuberculosis of the cervical lymph nodes. The retro-pharyngeal abscess was drained by opening the external abscess with which it communicated through a small opening.

The clinics are held at the Children's Hospital once a month, on Friday afternoons at 4.30. All physicians are invited. The dates of future clinics are January 12, February 9, March 9, April 13, May 11.

THE MEETINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Attention was called to the meetings of this Association last week.

The meeting on the afternoon of Friday of this week is of special interest to physicians and it is hoped that there will be a large attendance.

The speakers are Dr. R. P. Strong of Harvard University, Dr. A. B. Macallum of McGill University, Dr. C. T. Brues of the Bussey Institute, Harvard University, Dr. L. O. Howard of the United States Bureau of Entomology, Dr. C. W. Stiles of the United States Public Health Service and Dr. C. A. Kofoed of the University of California.

Miscellany.

RÉSUMÉ OF COMMUNICABLE DISEASES. NOVEMBER, 1922.

GENERAL PREVALENCE.

The more prevalent diseases showing an increase over the previous month are as follows: chicken-pox, diphtheria, measles, mumps, pneumonia (lobar), scarlet fever, whooping cough.

	Nov. 1922	Oct. 1922	Nov. 1921
Chicken-pox	664	199	646
Diphtheria	1263	1021	1185
Measles	1166	686	578
Mumps	449	188	241
Pneumonia, lobar ..	445	236	353
Scarlet fever	809	554	661
Whooping cough ...	1056	634	223

RARE DISEASES.

Anterior poliomyelitis was reported from Boston, 9; Cambridge, 2; Lawrence, 1; Lexington, 1; Lynn, 3; Northampton, 1; Orleans, 1; Somerville, 1; Waltham, 1; Woburn, 1; total, 21.

Anthrax was reported from Peabody, 1.

Dog-bite requiring anti-rabic treatment was reported from Boston, 1; Chelsea, 6; Lowell, 4; Salem, 6; total, 17.

Encephalitis lethargica was reported from Boston, 1; Everett, 1; Lawrence, 1; Lynn, 1; Malden, 1; Marlboro, 1; Peabody, 1; Quincy, 1; Salem, 1; W. Bridge-water, 1; total, 10.

Epidemic cerebrospinal meningitis was reported from Adams, 1; Boston, 7; E. Bridge-water, 1; Fall River, 2; Gardner, 1; Melrose, 1; New Bedford, 1; Springfield, 1; total, 15.

Hookworm was reported from Boston, 4.

Malaria was reported from Boston, 1; Douglas, 1; Walpole, 1; total, 3.

Pellagra was reported from Boston, 1.

Rabies was reported from Boston, 1; Medford, 1; total, 2.

Septic sore throat was reported from Arlington, 1; Boston, 3; Cambridge, 1; Fall River, 1; New Bedford, 1; total, 7.

Smallpox was reported from Hadley, 1.

Tetanus was reported from Lynn, 1; Worcester, 1; total, 2.

Trachoma was reported from Boston, 11; Lynn, 1; Plymouth, 1; total, 13.

Trichinosis was reported from Holyoke, 1.

Obituary.

HERBERT CLARK EMERSON, M. D.

Death has claimed Dr. Herbert C. Emerson of Springfield, president of the Springfield Hospital, bacteriologist and chemist. He died December 6, 1922, after an illness of a few weeks.

The son of Moses Emerson, of the Home Fire Insurance Co., of Boston, he was born in Claremont, N. H., December 19, 1865. He was prepared for college at Phillips Andover Academy, graduated at Amherst in 1889, and at Harvard Medical School in 1893. After serving as house officer at Boston City Hospital and Boston Lying-in Hospital he became second assistant physician at the New Hampshire Asylum for the Insane. Then he went abroad and studied pathology and bacteriology, chiefly in Berlin.

He settled in Springfield in 1897 and began health work for the city two years later, holding the positions of member of the Board of Health, city physician and analytical and consulting chemist. The reorganization of the city health department, subsequent to 1901, was largely due to Dr. Emerson's labors. He started a health laboratory. He also devoted much time to the Springfield Hospital, acting as bacteriologist, establishing a first-class laboratory and enlarging the activities of the hospital.

During the war Dr. Emerson served as fuel administrator for Springfield on appointment by J. J. Storrow, administrator for the State.

He was a member of the Country Club of Springfield; George Washington Chapter, Sons of American Revolution; the Century Club, the Colony Club, the Springfield Academy of Medicine, the American Medical Association and the Massachusetts Medical Society. He was also a member of the Engineering Society of Western Massachusetts.

Dr. Emerson leaves a widow, who was formerly Louise B. Whitcomb, and a son, Richards Haskell Emerson, a senior at Harvard.

RECENT DEATH.

DR. JOHN MARTIN MALONEY died of pneumonia after an illness of a few days at his home in Springfield, December 17, 1922, at the age of thirty-seven.

He was born in Springfield in 1885, had his education in the public schools and his M.D. from the University of Georgetown, Washington, D. C., in 1907. Settling in his native city, he was an interne at the Mercy Hospital and then began a general practice.

He was a member of the Hampden District Medical Society, American Legion, Knights of Columbus and Springfield Lodge, B. P. O. E.

He is survived by a widow and two young children.

Correspondence.

JUDGE BAKER FOUNDATION.

40 COURT STREET (SCOLLAY SQUARE), ROOM 1214.
President, Frederick P. Cabot; directors, William Healy, M.D., Augusta F. Bronner, Ph.D.; treasurer, Charles L. DeNormandie; trustees, Miss Edith N. Burleigh, Judge Frederick P. Cabot, Roy M. Cushman (Secretary), Charles L. DeNormandie, Dr. Walter E. Fernald, Mrs. Jessie D. Hodder, Judge Frank Leverson, Herbert C. Parsons, Judge Philip Rubenstein.

Boston, December 14, 1922.

Mr. Editor:

I am sending you under another cover some sample copies of the case studies which we are getting out under a grant from the Commonwealth Fund. I wonder if you would be good enough to review these or have someone else review them, in the MEDICAL AND SURGICAL JOURNAL. We are naturally anxious to have these case studies brought to the attention of those to whom they will be of the most value. I am enclosing herewith our circular letter sent out in June, which gives in detail the plan of the series. Seven studies have already been issued, and three more are

in press. The studies, as you will note, are issued periodically, approximately two each month.

Yours very truly,

WILLIAM HEALY.

My dear Sir:

The Judge Baker Foundation has just completed five years of work. During this period there have been scientifically studied 2800 cases, many intensively, and all have been followed up. The majority have come from the Boston Juvenile Court, the remainder from a variety of sources—child welfare agencies, school people, parents, etc. The problems presented have covered not only delinquency, but also questions of education, vocation, and minor behavior difficulties.

Because of the range of problems and because of our unusually favorable opportunity for study and observation of the results of treatment, we have been able to collect a vast amount of data which we think will be of great interest to students of education in general, as well as to those interested in delinquency.

Through a gift from the Commonwealth Fund of New York, it is now possible for us to publish some of our case material. We plan, between September and June, to publish twenty actually studied cases, followed over a period of years. This series will represent varied individual differences, such as those pertaining to physical and mental make-up, the latter particularly considering matters of special peculiarities and capacities, the specific delinquency involved, the type of treatment given, and many other points.

Each study will consist of a pamphlet. For the case presentation we have evolved a new form in the hope that it will not only make the case material clearer and more interesting, but also that it will prove most valuable in its adaptation for teaching purposes; it is to be printed on the left hand page, with the discussion on the right hand page. For class work the study will be issued in loose-leaf form, in order that the student may receive only the case material. He may make his own interpretations either on the opposite blank page or on interleaving paper, and later receive the printed discussion for comparison. Follow-up facts may similarly be withheld. For other readers the entire material is intact.

The price will be \$2.50 for the series of twenty. (Rate for orders of 10 or more series is \$2.00 for each series.) The price is made possible by our gift from the Commonwealth Fund. If you wish to subscribe to the series, will you kindly let us know on the enclosed blank form very soon?

We shall be very glad to send further information if you desire it.

Very sincerely yours,

WILLIAM HEALY.

AUGUSTA F. BRONNER.

[NOTE: The JOURNAL will publish a series of the case studies as submitted.]

TEST FOR PERFORATING GASTRIC ULCER.

December 13, 1922.

Mr. Editor:

Some months ago, after doing an operation in an emergency, for what we thought was an acute appendix, finding a perforation of the stomach, I wondered if any simple procedure would aid diagnosis in an obscure case like the above. As I have reason to believe it has never been used, would suggest, in obscure cases, immediately of the making small incision, the use of sterile litmus paper, and see if you get an acid reaction. If such were the case your diagnosis ought not to be hard to make. Trust-

ing that this suggestion may occasionally be of use to my professional brothers, I am

Very truly yours,

F. P. HEDNUT, M.D.

New Bedford, Mass.

In searching for information the following letter was received:

Dr. F. P. HEDNUT,

New Bedford, Mass.

A thorough search of various indexes, journals and textbooks has failed to reveal any reference to the use of litmus paper as a means of diagnosing perforation of the stomach. Most pathologists depend on signs of exudation and secondary inflammation to make the diagnosis.

Very likely the use of litmus paper would show the presence of acid. However, it does not seem safe to depend on such a reaction for the diagnosis of gastric perforation.

Very truly yours,

JOURNAL AMERICAN MEDICAL ASSOCIATION.

PASTEUR INSTITUTE SCHOLARSHIPS.

December 15, 1922.

Mr. Editor:

The enclosed, from Mrs. Bellamy Storer, may be of interest to the JOURNAL readers.

Sincerely,

MALCOLM STORER.

302 Beacon Street, Boston.

A society has been founded in Paris to promote the studies of young scientists at the Pasteur Institute, by establishing scholarships to be given to French students whose means do not permit them to defray the expenses of a two years' supplementary scientific course at the Institute. Dr. Caluette is anxious to receive also at the Pasteur Institute students from foreign countries and especially from the United States. He asks if the medical and scientific schools of America would establish scholarships, to enable students to attend the courses at the Pasteur Institute during two years. These courses include micro-biology, sero-therapeutics and their practical application, also the study of the uses of radium. These students will also be allowed to follow, at the Pasteur Hospital, the most scientific treatment of contagious diseases and also the treatment of cancer by radium. The Paris committee will personally welcome the foreign students, and assist them to establish themselves. For all information please address the Marquise de Chambrun, 19 Avenue Rapp, Paris. The regular courses at the Pasteur Institute begin in January. The men connected with the Institute at present are of the highest standing in their profession. One of them is the grandson of Pasteur, Dr. Pasteur Vallery-Radot, who at the early age of thirty-six is in the first rank of the medical profession of Paris.

As to the cost of these scholarships, it is estimated that 12,000 francs a year will cover all expenses, including the courses at the Institute; at the present rate of exchange this would be about \$1000, or \$2000 for a two years' scholarship.

The centenary of Pasteur seems a fitting time to inaugurate this international association of scientific students.

WALTER REED GENERAL HOSPITAL.

Washington, D. C.

A second course in Physio Therapy will be given at Walter Reed General Hospital, Washington, D. C., beginning February 27, 1923, and extending for a period of four months. It is open to women who have had at least a two-year training in an approved school of physical education. For further informa-

tion, apply to: The Commanding Officer, Walter Reed General Hospital, Department of Physio Therapy, Washington, D. C.

JAMES B. MONTGOMERY,
Major, M. C., U. S. Army,
Director of Physio Therapy.

UNITED STATES CIVIL SERVICE EXAMINATION.

JUNIOR PATHOLOGICAL TECHNICIAN.

The United States Civil Service Commission announces an open competitive examination for junior pathological technician, the receipt of applications to close January 16, 1923. A vacancy in the Army Medical Museum, War Department, Washington, D. C., at \$1800 a year (plus "bonus"), and vacancies in positions requiring similar qualifications, at this or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

SOCIETY MEETINGS.

DISTRICT SOCIETIES.

A list of society meetings is herewith published. This list will be changed on information furnished by the secretaries of the societies, and will appear in each issue.

Barnstable District:—Hyannis,—February 2, 1923, (Annual Meeting)—May 4, 1923.

Bristol South District:—Fall River,—May 3, 1923.

Essex North District:—Haverhill, (Semi-Annual Meeting)—January 3, 1923. Y. M. C. A. Building, Lawrence, (Annual Meeting)—May 2, 1923.

Meetings of the Suffolk District and the Boston Medical Library, at the Library:

December 27, 1922:—Surgical Meeting. "Surgical Lesions Occurring in Diabetics: Their Peculiarities and Management," Dr. Elliott P. Joslin, Boston. An account of the experience in this field of the major hospitals of Boston, by members of the staffs.

January 31, 1923:—Medical Meeting. "Epidemic Encephalitis," Dr. E. W. Taylor, Boston.

February 28, 1923:—Medical Meeting. "Colitis," Dr. Henry F. Jones, Boston.

March 28, 1923:—Surgical Meeting. "A Review of What Surgery Can Accomplish in Diseases of the Thoracic Organs, with a Forecast of the Future," Dr. Howard Lillenthal of New York.

April 26, 1923:—Annual Meeting. Election of Officers. "The Record of the Past Twelve Years in Syphilology, with a Forecast of the Future." A series of 10-minute papers. Dr. C. Morton Smith, Boston, will provide.

The Springfield Academy of Medicine meets the second Tuesday of each month. Schedule of speakers includes the following names: Dr. Alexia Carrel, Dr. W. B. Long, Dr. J. W. Williams, Dr. W. S. Thayer, and Dr. Barton Cooke, Hist. The date for each speaker has not been assigned.

Middlesex North District:—Meeting, Wednesday, January 31, 1923.

Middlesex East District:—Jan. 24, 1923. The Nursing Problem. Speaker to be announced later.

March 21, 1923. Mental Factors in Childhood. Paper by Dr. William Healy.

April 18, 1923. Interpretation of Laboratory Findings. Papers by Dr. E. G. Crabtree and one to be announced later.

May 9, 1923. Annual Meeting.

All meetings except the annual meeting will be held at the Harvard Club in Boston. A. E. Small, Secretary.

Worcester District Meetings are scheduled as follows:

January 10, 1923:—The meeting will be held at the Worcester State Hospital, Belmont Street, at 4:15 P.M. Programme: "A Discussion of Status Thyroideus-Lymphaticus and the Inherent Compensatory Possibilities," Dr. Walter Timme, New York City. Discussion will be opened by Dr. W. A. Bryan.

February 14, 1923:—The meeting will be held at the Worcester City Hospital at 4:15 P.M. The programme will consist of a series of papers by members of the staff.

March 14, 1923:—The meeting will be held at St. Vincent's Hospital at 8:15 P.M. The programme will consist of a series of papers by members of the staff.

April 11, 1923:—The meeting will be held at Memorial Hospital at 8:15 P.M., and the programme will consist of a series of papers by members of the staff.

May 9, 1923:—Annual meeting and banquet.

STATE, INTERSTATE AND NATIONAL SOCIETIES.

NEW ENGLAND PEDIATRIC SOCIETY:—The following are the dates for meetings the coming season. Each meeting is on the second Friday of the month at the Boston Medical Library: January 12, February 9, March 9, April 13 and May 11.

December 26-30, 1922:—American Association for Advancement of Science meets in Boston.

January, 1923:—Massachusetts Society of Examining Physicians (date and place undecided); Hilbert F. Day, Secretary. Massachusetts Association of Boards of Health, January 25, Annual Meeting, Boston; W. H. Allen, Mansfield, Mass., Secretary.

January, 1923:—Boston Association of Cardiac Clinics. Meeting January 18, 1923, at 8:15 P.M. Boston Lying-In Hospital (New Hospital). Subject: Pregnancy and Heart Disease.

January, 1923:—Boston Medical History Club will meet January 15, 1923.

February, 1923:—New England Dermatological Society Meeting, February 14, 1923, at 3:30 P.M., in the Skin Out-Patient Department, Massachusetts General Hospital; C. Guy Lane, Secretary.

February, 1923:—Boston Medical History Club will meet the third Monday of this month.

March, 1923:—Massachusetts Society of Examining Physicians (date and place undecided); Hilbert F. Day, Secretary.

March, 1923:—Boston Association of Cardiac Clinics. Meeting March 16, 1923, at 8:15 P.M. Boston City Hospital. Subject: Prevention and Relief of Heart Failure.

March, 1923:—Boston Medical History Club will meet the third Monday of this month.

April, 1923:—New England Dermatological Society Meeting, April 11, 1923, at 3:30 P.M., in the Surgical Amphitheatre, Boston City Hospital; C. Guy Lane, Secretary. Massachusetts Association of Boards of Health, April 26, 1923, Boston; W. H. Allen, Mansfield, Mass., Secretary.

April, 1923:—Boston Medical History Club will meet the third Monday of this month.

May, 1923:—Massachusetts Society of Examining Physicians (date and place undecided). American Pediatric Society Meeting, May 31, June 1 and 2, 1923, at French Lick Springs Hotel, French Lick, Ind.; H. C. Carpenter, Secretary.

May, 1923:—Boston Association of Cardiac Clinics. Meeting May 17, 1923, at 8:15 P.M. Children's Hospital. Subject: Rheumatism and Chorea and Heart Disease.

June, 1923:—American Medical Association, San Francisco, June 25-29, 1923; Alexander R. Craig, Chicago, Ill., Secretary.

July, 1923:—Massachusetts Association of Boards of Health, July 26, Nantasket; W. H. Allen, Mansfield, Mass., Secretary.

*Deceased September 2, 1922.

CALL AND INSPECT The New Stearns Knight ==SIX==

The long record of unsurpassed reliability of the Stearns Knight Car, four cylinder, is impressive. Physicians must have reliable service under all conditions. The Stearns Knight has always met this demand and will continue to do so in this Six with still greater efficiency.

The Coupe is especially adapted to a physician's needs. Other attractive bodies furnished in fours or sixes. You owe it to yourself to compare this car with *all others*.

TUFTS COLLEGE MEDICAL AND DENTAL SCHOOLS

The Tufts College Medical School offers a four-year course leading to the degree of Doctor of Medicine. The next session begins September 27, 1922. Students of both sexes are admitted upon presentation of an approved high school certificate and, in addition, college credit indicating two years' work in Chemistry, English, Physics, Biology, and French or German.

STEPHEN RUSHMORE, M.D., *Dean*.

For further information, apply to FRANK E. HASKINS, M.D., *Secretary*, 416 Huntington Avenue, Boston 17, Mass.

Beginning January, 1921, all candidates for admission to the Tufts College Dental School must present evidence of having attended one year in a recognized college or university, and to have passed the subjects of the year. These subjects must include Physics, Chemistry, Biology and English.

Tufts College has arranged a One-Year Pre-Dental Course which fulfills these requirements. A special bulletin describing the course will be sent upon application.

WILLIAM RICE, D.M.D., *Dean*.

NEW YORK EYE AND EAR INFIRMARY

Special post-graduate instruction in Eye, Ear, Nose and Throat. Six months' course, beginning August 1st. Also short time courses can be arranged for. For particulars address

Massachusetts General Hospital

Pay Consultation Clinic

To aid in diagnosis in cases requiring the advice of several specialists, members of the staff of the Massachusetts General Hospital will hold clinics at the hospital Tuesday and Friday afternoons at 1.30 P.M. Physicians desiring to make use of the clinic should refer their cases by letter, addressed to the Consultation Clinic, giving a brief history. The object being to establish a diagnosis, no treatment will be given, nor will patients be admitted to the hospital except to complete an examination which cannot be completed in the limited time of the clinic.

Patients are referred back to the doctor who sends them to us. Several visits may be necessary to establish a diagnosis, and when ordered by the clinic staff, no additional charge will be made for such visits. Upon completion of the examination a report will be sent to the doctor who refers the case.

No appointment is necessary.

No treatment given.

Hours: Tuesdays and Fridays, 1.30 P.M. to 2 P.M.

A letter from a doctor is required in every case.

Consultation	\$10.00
X-Ray	5.00 to 10.00
Laboratory examination	2.00
Cystoscopy	3.00
Electrocardiogram	10.00

Wet nurses may be obtained by telephoning to

THE DIRECTORY, Brookline 2930

Buying Power of Our Members

There are 4413 subscribers, including members of the Massachusetts Medical Society and readers of this Journal, located in every important city and town of this State.

This means 4413 circles of practice, which touch and influence over 2,206,500 people in the homes, industries and institutions throughout the State.

Think of the BUYING POWER of these physicians! If their average expenditure is only \$1000, that amounts to \$4,413,000 a year. But medical supplies bought on physicians' prescriptions and goods purchased on their orders or recommendations for sanitariums, hospitals, boards of health, etc., would fully equal that amount,—or a total of \$8,000,000.

If members will give preference in all their buying to advertisers in their State Medical Journal, other advertisers will want space, and the publishers can then print a LARGER and BETTER Journal.

If you do not find advertised here the goods you want, please write the Journal. We will secure the information for you.

The Boston Medical and Surgical Journal will publish cards of physicians calling attention to the street and telephone number and the type of practice similar to the following:

DR. JOHN DOE

99 Blank Street, Boston Tel. B. B. 78654

Practice Limited to Surgery

Any form of practice may be specified or the name alone may appear if preferred.

The object is to furnish practitioners with correct addresses and names for easy reference. Each card will take a three-fourths inch space.

The price for cards of this size is 75c for three lines, per insertion, or thirty dollars per year.

Larger space will be quoted on application. The right is reserved to reject any application for space.
